DESCRIPTION

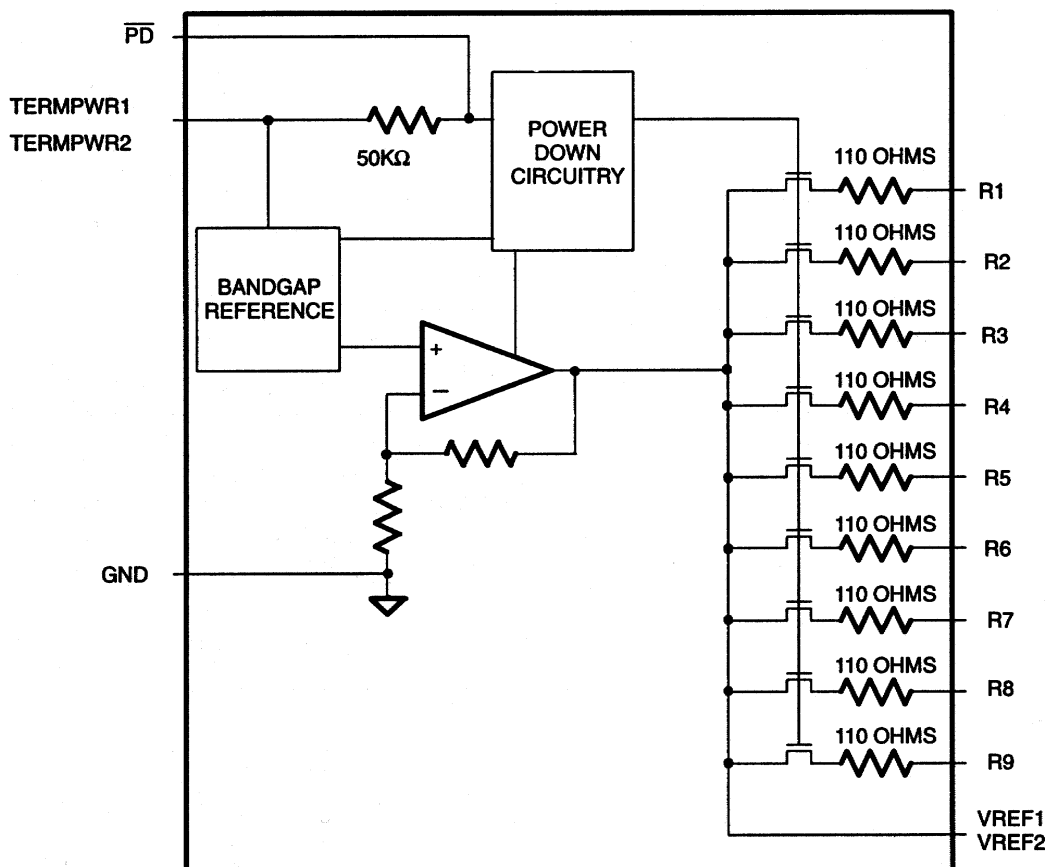

Fast SCSI and Ultra SCSI require the use of active terminations at both ends of every cable segment in a SCSI system with single-ended drivers and receivers. The DS21T07 SCSI Terminator, which is fully compliant with these standards, enables the designer to gain the benefits of active termination: greater immunity to voltage drops on the TERMPWR (TERMination PoWeR) line, enhanced high-level noise immunity, intrinsic TERMPWR decoupling, and very low quiescent current consumption. The DS21T07 integrates a regulator and nine precise switched 110 ohms termination resistors into a monolithic IC. The DS21T07 can be electrically isolated from the SCSI bus without physical removal from the SCSI device.

FUNCTIONAL DESCRIPTION

The DS21T07 consists of a bandgap reference, buffer amplifier, and nine termination resistors (Figure 1). The bandgap reference circuit produces a precise 2.55V level which is fed to a buffer amplifier. The buffer produces a 2.85V level and is capable of sourcing at least 24 mA into each of the termination resistors when the signal line is low (active). When the driver for a given signal line turns off, the terminator will pull the signal line to 2.85V (quiescent state). To handle actively negated SCSI signals, the buffer can sink at least 200 mA, and V_{REF} will move less than 60 mV. When all lines settle in the quiescent state, the regulator will consume about 5 mA. When the DS21T07 is put into power-down mode by bringing \overline{PD} low, the power-down circuitry will turn off the transistors on each signal line. This will isolate the DS21T07 from the signal lines and effectively remove it from the circuit. The power-down pin (\overline{PD}) has an internal 50K Ω pullup resistor. To place the DS21T07 into an active state, the \overline{PD} pin should be left open circuited. When installed on disk drives or RAID system components, the DS21T07 will not affect the SCSI bus during a hot plug operation.

To ensure proper operation, both the TERMPWR1 and TERMPWR2 pins must be connected to the SCSI bus TERMPWR line and both the VREF1 and VREF2 pins must be tied together externally. Each DS21T07 requires a 4.7 μ F capacitor connected between the VREF pins and ground. Figure 2 details a typical SCSI bus configuration. In an 8-bit wide SCSI bus arrangement, two DS21T07's would be needed at each end of the SCSI cable in order to terminate the 18 active signal lines. In a 16-bit wide SCSI bus arrangement, three DS21T07's would be needed at each end of the SCSI cable in order to terminate the 27 active signal lines.

NOTES:

1. C1 = 4.7 μ F tantalum
C2 = 2.2 μ F tantalum or 4.7 μ F aluminum
2. If the DS21T07 is to be embedded into a peripheral that will act as a target on a SCSI bus, it is that recommended TERMPWR be derived from the SCSI cable, not generated locally. In this configuration, if a power failure occurs in the peripheral, it will not affect the bus.
3. A high frequency bypass capacitor (0.1 μ F recommended) can be added in parallel to C1 for applications using fast rise/fall time drivers.
