THE DATASHEET OF

LTC3830ES#TRPBF

High Power Step-Down Synchronous DC/DC Controllers for Low Voltage Operation

FEATURES

- **High Power Switching Regulator Controller for 3.3V-5V to 1.xV-3.xV Step-Down Applications**
- **No Current Sense Resistor Required**
- **Low Input Supply Voltage Range: 3V to 8V**
- **Maximum Duty Cycle >91% Over Temperature**
- All N-Channel External MOSFETs
- Excellent Output Regulation: ±1% Over Line, Load and Temperature Variations
- High Efficiency: Over 95% Possible
- Adjustable or Fixed 3.3V Output (16-Pin Version)
- Programmable Fixed Frequency Operation: 100kHz to 500kHz
- External Clock Synchronization
- Soft-Start (16-Pin Version and LTC3830-1)
- Low Shutdown Current: <10μA
- Overtemperature Protection
- Available in S8, S16 and SSOP-16 Packages

APPLICATIONS

- CPU Power Supplies
- Multiple Logic Supply Generator
- Distributed Power Applications
- High Efficiency Power Conversion

DESCRIPTION

The LTC®3830/LTC3830-1 are high power, high efficiency switching regulator controllers optimized for 3.3V-5V to 1.xV-3.xV step-down applications. A precision internal reference and feedback system provide ±1% output regulation over temperature, load current and line voltage variations. The LTC3830/LTC3830-1 use a synchronous switching architecture with N-channel MOSFETs. Additionally, the chip senses output current through the drain-source resistance of the upper N-channel FET, providing an adjustable current limit without a current sense resistor.

The LTC3830/LTC3830-1 operate with an input supply voltage as low as 3V and with a maximum duty cycle of >91% over temperature. They include a fixed frequency PWM oscillator for low output ripple operation. The 200kHz free-running clock frequency can be externally adjusted or synchronized with an external signal from 100kHz to 500kHz. In shutdown mode, the LTC3830 supply current drops to <10μA. The LTC3830-1 differs from the LTC3830 S8 version by replacing shutdown with a soft-start function.

For a similar, pin compatible DC/DC converter with an output voltage as low as 0.6V, please refer to the LTC3832.

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: All currents into device pins are positive; all currents out of device pins are negative. All voltages are referenced to ground unless otherwise specified.

Note 3: Supply current in normal operation is dominated by the current needed to charge and discharge the external FET gates. This will vary with the LTC3830 operating frequency, operating voltage and the external FETs used.

Note 4: The open-loop DC gain and transconductance from the $SENSE^+$ and $SENSE^-$ pins to COMP pin will be $(A_V)(1.265/3.3)$ and $(g_m)(1.265/3.3)$ respectively.

Note 5: Rise and fall times are measured using 10% and 90% levels. Duty cycle and nonoverlap times are measured using 50% levels.

Note 6: Guaranteed by design, not subject to test.

Note 7: PV_{CC1} must be higher than V_{CC} by at least 2.5V for G1 to operate at 95% maximum duty cycle and for the current limit protection circuit to be active.

Note 8: The current limiting amplifier can sink but cannot source current. Under normal (not current limited) operation, the output current will be zero.

Note 9: The LTC3830E/LTC3830-1E are guaranteed to meet performance specifications from 0°C to 70°C. Specifications over the –40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls.

Note 10: The minimum and maximum limits for I_{MAX} over temperature includes the intentional temperature coefficient of 3300ppm/°C. This induced temperature coefficient counteracts the typical temperature coefficient of the external power MOSFET on-resistance. This results in a relatively flat current limit over temperature for the application.

Note 11: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 125°C when overtemperature protection is active. Continuous operation above the specified maximum operating temperature may impair device reliability.

PIN FUNCTIONS (16-Lead LTC3830/8-Lead LTC3830/LTC3830-1)

G1 (Pin 1/Pin 1/Pin 1): Top Gate Driver Output. Connect this pin to the gate of the upper N-channel MOSFET, Q1. This output swings from PGND to PV_{CC1}. It remains low if G2 is high or during shutdown mode.

PV_{CC1} (Pin 2/Pin 2/Pin 2): Power Supply Input for G1. Connect this pin to a potential of at least $V_{IN} + V_{GS(ON)(Q1)}$. This potential can be generated using an external supply or charge pump.

PGND (Pin 3/Pin 3/Pin 3): Power Ground. Both drivers return to this pin. Connect this pin to a low impedance ground in close proximity to the source of Q2. Refer to the Layout Consideration section for more details on PCB layout techniques. The LTC3830-1 and the 8-lead LTC3830 have PGND and GND tied together internally at Pin 3.

GND (Pin 4/Pin 3/Pin 3): Signal Ground. All low power internal circuitry returns to this pin. To minimize regulation errors due to ground currents, connect GND to PGND right at the LTC3830.

$SENSE^-$, FB, $SENSE^+$ (Pins 5, 6, 7/Pin 4/Pin 4): These three pins connect to the internal resistor divider and input of the error amplifier. To use the internal divider to set the output voltage to 3.3V, connect $SENSE^+$ to the positive terminal of the output capacitor and $SENSE^-$ to the negative terminal. FB should be left floating. To use an external resistor divider to set the output voltage, float $SENSE^+$ and $SENSE^-$ and connect the external resistor divider to FB. The internal resistor divider is not included in the LTC3830-1 and the 8-lead LTC3830.

$\overline{SHDN}$ (Pin 8/Pin 5/NA): Shutdown. A TTL compatible low level at $\overline{SHDN}$ for longer than 100µs puts the LTC3830 into shutdown mode. In shutdown, G1 and G2 go low, all internal circuits are disabled and the quiescent current drops to 10µA max. A TTL compatible high level at $\overline{SHDN}$ allows the part to operate normally. This pin also doubles as an external clock input to synchronize the internal oscillator with an external clock. The shutdown function is disabled in the LTC3830-1.

SS (Pin 9/NA/Pin 5): Soft-Start. Connect this pin to an external capacitor, C_{SS}, to implement a soft-start function. If the LTC3830 goes into current limit, C_{SS} is discharged to reduce the duty cycle. C_{SS} must be selected such that during power-up, the current through Q1 will not exceed the current limit level. The soft-start function is disabled in the 8-lead LTC3830.

COMP (Pin 10/Pin 6/Pin 6): External Compensation. This pin internally connects to the output of the error amplifier and input of the PWM comparator. Use a RC + C network at this pin to compensate the feedback loop to provide optimum transient response.

PIN FUNCTIONS

FREQSET (Pin 11/NA/NA): Frequency Set. Use this pin to adjust the free-running frequency of the internal oscillator. With the pin floating, the oscillator runs at about 200kHz. A resistor from FREQSET to ground speeds up the oscillator; a resistor to V_{CC} slows it down.

I_{MAX} (Pin 12/NA/NA): Current Limit Threshold Set. I_{MAX} sets the threshold for the internal current limit comparator. If I_{FB} drops below I_{MAX} with G1 on, the LTC3830 goes into current limit. I_{MAX} has an internal 12μA pull-down to GND. Connect this pin to the main V_{IN} supply at the drain of Q1, through an external resistor to set the current limit threshold. Connect a 0.1μF decoupling capacitor across this resistor to filter switching noise.

I_{FB} (Pin 13/NA/NA): Current Limit Sense. Connect this pin to the switching node at the source of Q1 and the drain of Q2 through a 1k resistor. The 1k resistor is required to prevent voltage transients from damaging I_{FB}.This pin is used for sensing the voltage drop across the upper N-channel MOSFET, Q1.

V_{CC} (Pin 14/Pin 7/Pin 7): Power Supply Input. All low power internal circuits draw their supply from this pin. Connect this pin to a clean power supply, separate from the main V_{IN} supply at the drain of Q1. This pin requires a 4.7μF bypass capacitor. The LTC3830-1 and the 8-lead LTC3830 have V_{CC} and PV_{CC2} tied together at Pin 7 and require a 10μF bypass capacitor to GND.

PV_{CC2} (Pin 15/Pin 7/Pin 7): Power Supply Input for G2. Connect this pin to the main high power supply.

G2 (Pin 16/Pin 8/Pin 8): Bottom Gate Driver Output. Connect this pin to the gate of the lower N-channel MOSFET, Q2. This output swings from PGND to PV_{CC2}. It remains low when G1 is high or during shutdown mode. To prevent output undershoot during a soft-start cycle, G2 is held low until G1 first goes high. (FFBG in Block Diagram.)

TEST CIRCUITS

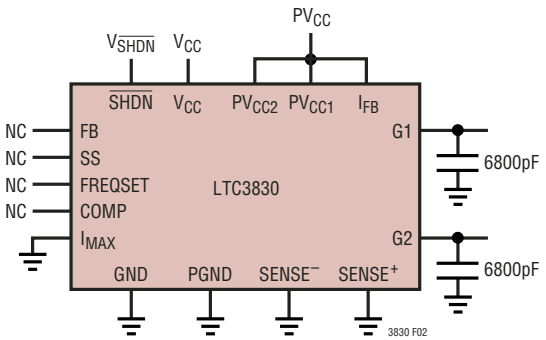

Figure 2

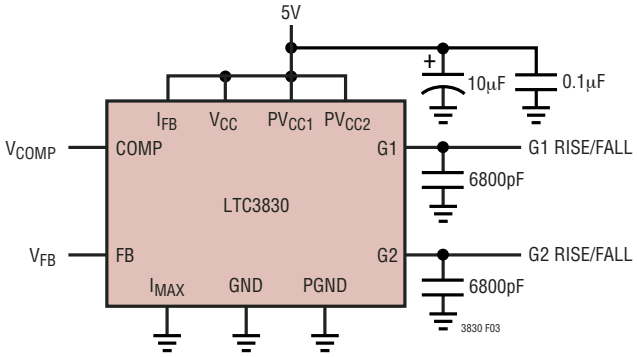

Figure 3

APPLICATIONS INFORMATION

OVERVIEW

The LTC3830 is a voltage mode feedback, synchronous switching regulator controller (see Block Diagram) designed for use in high power, low voltage step-down (buck) converters. It includes an onboard PWM generator, a precision reference trimmed to ±0.8%, two high power MOSFET gate drivers and all necessary feedback and control circuitry to form a complete switching regulator circuit. The PWM loop nominally runs at 200kHz.

The 16-lead versions of the LTC3830 include a current limit sensing circuit that uses the topside external N-channel power MOSFET as a current sensing element, eliminating the need for an external sense resistor.

Also included in the 16-lead version and the LTC3830-1 is an internal soft-start feature that requires only a single external capacitor to operate. In addition, 16-lead parts feature an adjustable oscillator that can free run or synchronize to external signal with frequencies from 100kHz to 500kHz, allowing added flexibility in external component selection. The 8-lead version does not include current limit, internal soft-start and frequency adjustability. The LTC3830-1 does not include current limit, frequency adjustability, external synchronization and the shutdown function.

THEORY OF OPERATION

Primary Feedback Loop

The LTC3830/LTC3830-1 sense the output voltage of the circuit at the output capacitor and feeds this voltage back to the internal transconductance error amplifier, ERR, through a resistor divider network. The error amplifier compares the resistor-divided output voltage to the internal 1.265V reference and outputs an error signal to the PWM comparator. This error signal is compared with a fixed frequency ramp waveform, from the internal oscillator, to generate a pulse width modulated signal. This PWM signal drives the external MOSFETs through the G1 and G2 pins. The resulting chopped waveform is filtered by L_O and C_{OUT} which closes the loop. Loop compensation is achieved with an external compensation network at the COMP pin, the output node of the error amplifier.

MIN, MAX Feedback Loops

Two additional comparators in the feedback loop provide high speed output voltage correction in situations where the error amplifier may not respond quickly enough. MIN compares the feedback signal to a voltage 40mV below the internal reference. If the signal is below the comparator threshold, the MIN comparator overrides the error amplifier and forces the loop to maximum duty cycle, >91%.

APPLICATIONS INFORMATION

Similarly, the MAX comparator forces the output to 0% duty cycle if the feedback signal is greater than 40mV above the internal reference. To prevent these two comparators from triggering due to noise, the MIN and MAX comparators' response times are deliberately delayed by two to three microseconds. These two comparators help prevent extreme output perturbations with fast output load current transients, while allowing the main feedback loop to be optimally compensated for stability.

Thermal Shutdown

The LTC3830/LTC3830-1 have a thermal protection circuit that disables both gate drivers if activated. If the chip junction temperature reaches 150°C, both G1 and G2 are pulled low. G1 and G2 remain low until the junction temperature drops below 125°C, after which, the chip resumes normal operation.

Soft-Start and Current Limit

The 16-lead LTC3830 devices include a soft-start circuit that is used for start-up and current limit operation. The LTC3830-1 only has the soft-start function; the current limit function is disabled. The 8-lead LTC3830 has both the soft-start and current limit function disabled. The SS pin requires an external capacitor, C_{SS}, to GND with the value determined by the required soft-start time. An internal 12μA current source is included to charge C_{SS}. During power-up, the COMP pin is clamped to a diode drop (B-E junction of QSS in the Block Diagram) above the voltage at the SS pin. This prevents the error amplifier from forcing the loop to maximum duty cycle. The LTC3830/LTC3830-1 operate at low duty cycle as the SS pin rises above 0.6V ($V_{COMP} \approx 1.2V$). As SS continues to rise, QSS turns off and the error amplifier takes over to regulate the output. The MIN comparator is disabled during soft-start to prevent it from overriding the soft-start function.

The 16-lead LTC3830 devices include yet another feedback loop to control operation in current limit. Just before every falling edge of G1, the current comparator, CC, samples and holds the voltage drop measured across the external upper MOSFET, Q1, at the I_{FB} pin. CC compares the voltage at I_{FB} to the voltage at the I_{MAX} pin. As the peak current rises, the measured voltage across Q1 increases due to the drop across the $R_{DS(ON)}$ of Q1. When the voltage at I_{FB} drops below I_{MAX}, indicating that Q1's drain current has exceeded the maximum level, CC starts to pull current out of C_{SS}, cutting the duty cycle and controlling the output current level. The CC comparator pulls current out of the SS pin in proportion to the voltage difference between I_{FB} and I_{MAX}. Under minor overload conditions, the SS pin falls gradually, creating a time delay before current limit takes effect. Very short, mild overloads may not affect the output voltage at all. More significant overload conditions allow the SS pin to reach a steady state, and the output remains at a reduced voltage until the overload is removed. Serious overloads generate a large overdrive at CC, allowing it to pull SS down quickly and preventing damage to the output components. By using the $R_{DS(ON)}$ of Q1 to measure the output current, the current limiting circuit eliminates an expensive discrete sense resistor that would otherwise be required. This helps minimize the number of components in the high current path.

The current limit threshold can be set by connecting an external resistor R_{IMAX} from the I_{MAX} pin to the main V_{IN} supply at the drain of Q1. The value of R_{IMAX} is determined by:

$$R_{IMAX} = (I_{LMAX})(R_{DS(ON)Q1})/I_{IMAX}$$

where:

$I_{LMAX} = I_{LOAD} + (I_{RIPPLE}/2)$

I_{LOAD} = Maximum load current

I_{RIPPLE} = Inductor ripple current

$$= \frac{(V_{IN} - V_{OUT})(V_{OUT})}{(f_{OSC})(L_O)(V_{IN})}$$

f_{OSC} = LTC3830 oscillator frequency = 200kHz

L_O = Inductor value

$R_{DS(ON)Q1}$ = On-resistance of Q1 at I_{LMAX}

I_{IMAX} = Internal 12μA sink current at I_{MAX}

APPLICATIONS INFORMATION

The $R_{DS(ON)}$ of Q1 usually increases with temperature. To keep the current limit threshold constant, the internal 12μA sink current at I_{MAX} is designed with a positive temperature coefficient to provide first order correction for the temperature coefficient of $R_{DS(ON)Q1}$.

In order for the current limit circuit to operate properly and to obtain a reasonably accurate current limit threshold, the I_{IMAX} and I_{FB} pins must be Kelvin sensed at Q1's drain and source pins. In addition, connect a 0.1μF decoupling capacitor across R_{IMAX} to filter switching noise. Otherwise, noise spikes or ringing at Q1's source can cause the actual current limit to be greater than the desired current limit set point. Due to switching noise and variation of $R_{DS(ON)}$, the actual current limit trip point is not highly accurate. The current limiting circuitry is primarily meant to prevent damage to the power supply circuitry during fault conditions. The exact current level where the limiting circuit begins to take effect will vary from unit to unit as the $R_{DS(ON)}$ of Q1 varies. Typically, $R_{DS(ON)}$ varies as much as ±40% and with ±25% variation on the LTC3830's I_{MAX} current, this can give a ±65% variation on the current limit threshold.

The $R_{DS(ON)}$ is high if the V_{GS} applied to the MOSFET is low. This occurs during power up, when PV_{CC1} is ramping up. To prevent the high $R_{DS(ON)}$ from activating the current limit, the LTC3830 disables the current limit circuit if PV_{CC1} is less than 2.5V above V_{CC}. To ensure proper operation of the current limit circuit, PV_{CC1} must be at least 2.5V above V_{CC} when G1 is high. PV_{CC1} can go low when G1 is low, allowing the use of an external charge pump to power PV_{CC1}.

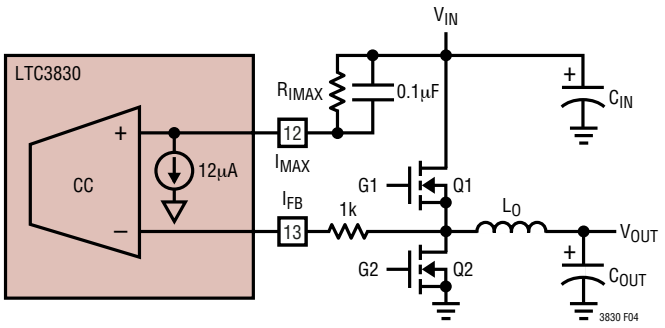

Figure 4. Current Limit Setting

Oscillator Frequency

The LTC3830 includes an onboard current controlled oscillator that typically free-runs at 200kHz. The oscillator frequency can be adjusted by forcing current into or out of the FREQSET pin. With the pin floating, the oscillator runs at about 200kHz. Every additional 1μA of current into/out of the FREQSET pin decreases/increases the frequency by 10kHz. The pin is internally servoed to 1.265V, connecting a 50k resistor from FREQSET to ground forces 25μA out of the pin, causing the internal oscillator to run at approximately 450kHz. Forcing an external 10μA current into FREQSET cuts the internal frequency to 100kHz. An internal clamp prevents the oscillator from running slower than about 50kHz. Tying FREQSET to V_{CC} forces the chip to run at this minimum speed. The LTC3830-1 and the 8-lead LTC3830 do not have this frequency adjustment function.

Shutdown

The LTC3830 includes a low power shutdown mode, controlled by the logic at the $\overline{SHDN}$ pin. A high at $\overline{SHDN}$ allows the part to operate normally. A low level at $\overline{SHDN}$ for more than 100μs forces the LTC3830 into shutdown mode. In this mode, all internal switching stops, the COMP and SS pins pull to ground and Q1 and Q2 turn off. The LTC3830 supply current drops to <10μA, although off-state leakage in the external MOSFETs may cause the total V_{IN} current to be some what higher, especially at elevated temperatures. If $\overline{SHDN}$ returns high, the LTC3830 reruns a soft-start cycle and resumes normal operation. The LTC3830-1 does not have this shutdown function.

APPLICATIONS INFORMATION

External Clock Synchronization

The LTC3830 $\overline{SHDN}$ pin doubles as an external clock input for applications that require a synchronized clock. An internal circuit forces the LTC3830 into external synchronization mode if a negative transition at the $\overline{SHDN}$ pin is detected. In this mode, every negative transition on the $\overline{SHDN}$ pin resets the internal oscillator and pulls the ramp signal low, this forces the LTC3830 internal oscillator to lock to the external clock frequency. The LTC3830-1 does not have this external synchronization function.

The LTC3830 internal oscillator can be externally synchronized from 100kHz to 500kHz. Frequencies above 300kHz can cause a decrease in the maximum obtainable duty cycle as rise/fall time and propagation delay take up a larger percentage of the switch cycle. Circuits using these frequencies should be checked carefully in applications where operation near dropout is important—like 3.3V to 2.5V converters. The low period of this clock signal must not be >100µs, or else the LTC3830 enters shutdown mode.

Figure 5 describes the operation of the external synchronization function. A negative transition at the $\overline{SHDN}$ pin forces the internal ramp signal low to restart a new PWM cycle. Notice that with the traditional sync method, the ramp amplitude is lowered as the external clock frequency goes higher. The effect of this decrease in ramp amplitude increases the open-loop gain of the controller feedback loop. As a result, the loop crossover frequency increases and it may cause the feedback loop to be unstable if the phase margin is insufficient.

To overcome this problem, the LTC3830 monitors the peak voltage of the ramp signal and adjusts the oscillator charging current to maintain a constant ramp peak.

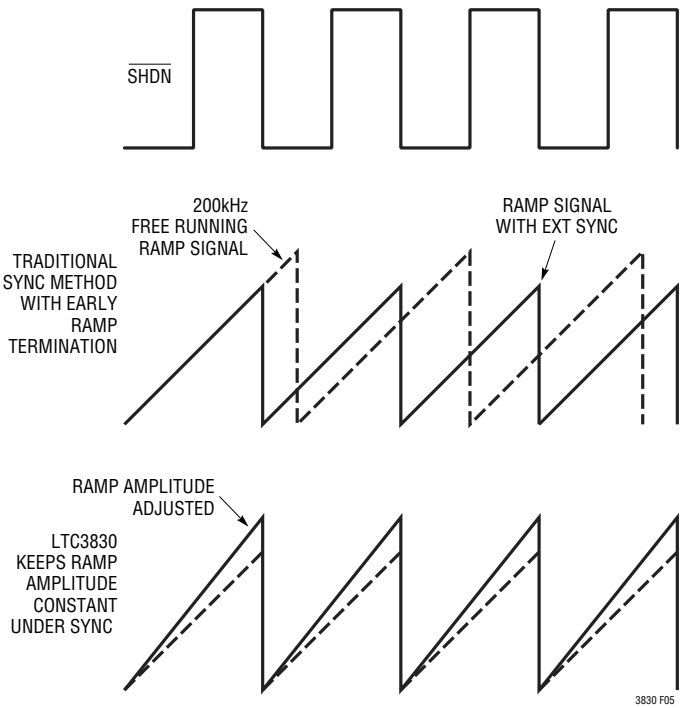

Figure 5. External Synchronization Operation

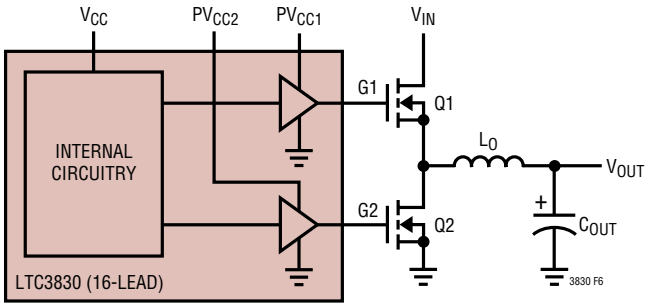

Figure 6. 16-Lead Power Supplies

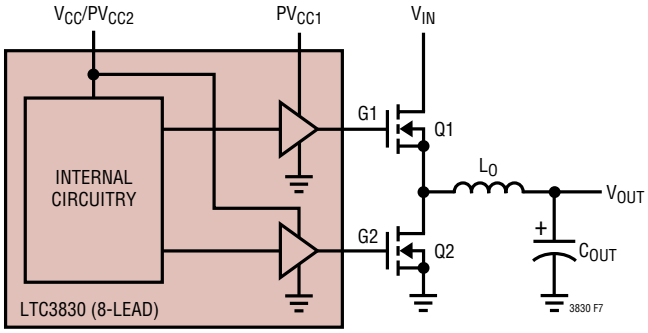

Figure 7. 8-Lead Power Supplies

APPLICATIONS INFORMATION

Input Supply Considerations/Charge Pump

The 16-lead LTC3830 requires four supply voltages to operate: V_{IN} for the main power input, PV_{CC1} and PV_{CC2} for MOSFET gate drive and a clean, low ripple V_{CC} for the LTC3830 internal circuitry (Figure 6). The LTC3830-1 and the 8-lead LTC3830 have the PV_{CC2} and V_{CC} pins tied together inside the package (Figure 7). This pin, brought out as V_{CC}/PV_{CC2} , has the same low ripple requirements as the 16-lead part, but must also be able to supply the gate drive current to Q2.

In many applications, V_{CC} can be powered from V_{IN} through an RC filter. This supply can be as low as 3V. The low quiescent current (typically 800μA) allows the use of relatively large filter resistors and correspondingly small filter capacitors. 100Ω and 4.7μF usually provide adequate filtering for V_{CC}. For best performance, connect the 4.7μF bypass capacitor as close to the LTC3830 V_{CC} pin as possible.

Gate drive for the top N-channel MOSFET Q1 is supplied from PV_{CC1}. This supply must be above V_{IN} (the main power supply input) by at least one power MOSFET $V_{GS(ON)}$ for efficient operation. An internal level shifter allows PV_{CC1} to operate at voltages above V_{CC} and V_{IN}, up to 14V maximum. This higher voltage can be supplied with a separate supply, or it can be generated using a charge pump.

Gate drive for the bottom MOSFET Q2 is provided through PV_{CC2} for the 16-lead LTC3830 or V_{CC}/PV_{CC2} for the LTC3830-1 and the 8-lead LTC3830. This supply only needs to be above the power MOSFET $V_{GS(ON)}$ for efficient operation. PV_{CC2} can also be driven from the same supply/charge pump for the PV_{CC1}, or it can be connected to a lower supply to improve efficiency.

Figure 8 shows a tripling charge pump circuit that can be used to provide $2V_{IN}$ and $3V_{IN}$ gate drive for the external top and bottom MOSFETs respectively. These should fully enhance MOSFETs with 5V logic level thresholds. This circuit provides $3V_{IN} – 3V_F$ to PV_{CC1} while Q1 is ON and $2V_{IN} – 2V_F$ to PV_{CC2} where V_F is the forward voltage of the Schottky diodes. The circuit requires the use of Schottky diodes to minimize forward drop across the diodes at start-up. The tripling charge pump circuit can rectify any ringing at the drain of Q2 and provide more than $3V_{IN}$ at PV_{CC1}; a 12V zener diode should be included from PV_{CC1} to PGND to prevent transients from damaging the circuitry at PV_{CC1} or the gate of Q1.

The charge pump capacitors refresh when the G2 pin goes high and the switch node is pulled low by Q2. The G2 on-time becomes narrow when LTC3830 operates at maximum duty cycle (95% typical), which can occur if the input supply rises more slowly than the soft-start capacitor or the input voltage droops during load transients. If the G2 on-time gets so narrow that the switch node fails to pull completely to ground, the charge pump voltage may collapse or fail to start, causing excessive dissipation in external MOSFET Q1. This is most likely with low V_{CC} voltages and high switching frequencies, coupled with large external MOSFETs which slow the G2 and switch node slew rates.

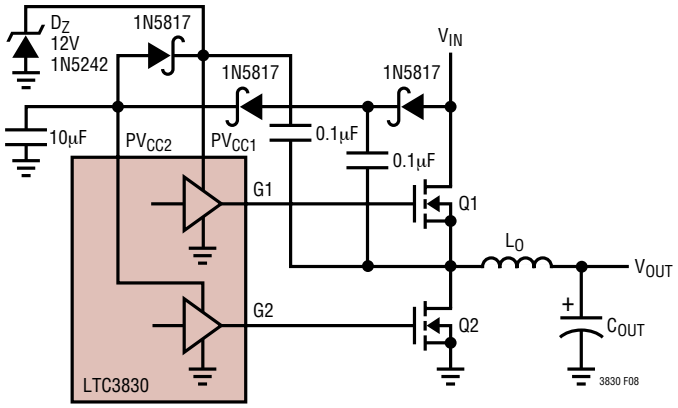

Figure 8. Tripling Charge Pump

APPLICATIONS INFORMATION

The LTC3830/LTC3830-1 overcomes this problem by sensing the PV_{CC1} voltage when G1 is high. If PV_{CC1} is less than (V_{CC} + 2.5V), the maximum G1 duty cycle is reduced to 70% by clamping the COMP pin at 1.8V (QC in BLOCK DIAGRAM). This increases the G2 on time and allows the charge pump capacitor to be refreshed.

For Applications using an external supply to power PV_{CC1}, this supply must also be higher than V_{CC} by at least 2.5V to insure normal operation.

For applications with a 5V or higher V_{IN} supply, PV_{CC2} can be tied to V_{IN} if a logic level MOSFET is used. PV_{CC1} can be supplied using a doubling charge pump as shown in Figure 9. This circuit provides $2V_{IN} – V_F$ to PV_{CC1} while Q1 is ON. Figure 12 shows a typical 5V to 3.3V application using a doubling charge pump to generate PV_{CC1}.

Power MOSFETs

Two N-channel power MOSFETs are required for most LTC3830 circuits. These should be selected based primarily on threshold voltage and on-resistance considerations. Thermal dissipation is often a secondary concern in high efficiency designs. The required MOSFET threshold should be determined based on the available power supply voltages and/or the complexity of the gate drive charge pump scheme. In 3.3V input designs where

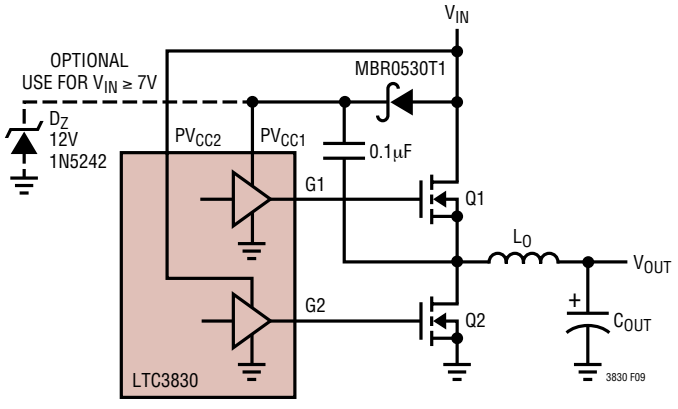

Figure 9. Doubling Charge Pump

an auxiliary 12V supply is available to power PV_{CC1} and PV_{CC2}, standard MOSFETs with $R_{DS(ON)}$ specified at V_{GS} = 5V or 6V can be used with good results. The current drawn from this supply varies with the MOSFETs used and the LTC3830's operating frequency, but is generally less than 50mA.

LTC3830 applications that use 5V or lower V_{IN} voltage and a doubling/tripling charge pump to generate PV_{CC1} and PV_{CC2}, do not provide enough gate drive voltage to fully enhance standard power MOSFETs. Under this condition, the effective MOSFET $R_{DS(ON)}$ may be quite high, raising the dissipation in the FETs and reducing efficiency. Logic level FETs are the recommended choice for 5V or lower voltage systems. Logic level FETs can be fully enhanced with a doubler/tripling charge pump and will operate at maximum efficiency.

After the MOSFET threshold voltage is selected, choose the $R_{DS(ON)}$ based on the input voltage, the output voltage, allowable power dissipation and maximum output current. In a typical LTC3830 circuit, operating in continuous mode, the average inductor current is equal to the output load current. This current flows through either Q1 or Q2 with the power dissipation split up according to the duty cycle:

$$DC(Q1) = \frac{V_{OUT}}{V_{IN}}$$

$$DC(Q2) = 1 - \frac{V_{OUT}}{V_{IN}} = \frac{V_{IN} - V_{OUT}}{V_{IN}}$$

The $R_{DS(ON)}$ required for a given conduction loss can now be calculated by rearranging the relation $P = I^2R$.

$$R_{DS(ON)Q1} = \frac{P_{MAX(Q1)}}{DC(Q1) \bullet (I_{LOAD})^2} = \frac{V_{IN} \bullet P_{MAX(Q1)}}{V_{OUT} \bullet (I_{LOAD})^2}$$

$$R_{DS(ON)Q2} = \frac{P_{MAX(Q2)}}{DC(Q2) \bullet (I_{LOAD})^2} = \frac{V_{IN} \bullet P_{MAX(Q2)}}{(V_{IN} - V_{OUT}) \bullet (I_{LOAD})^2}$$

APPLICATIONS INFORMATION

P_{MAX} should be calculated based primarily on required efficiency or allowable thermal dissipation. A typical high efficiency circuit designed for 5V input and 3.3V at 10A output might allow no more than 3% efficiency loss at full load for each MOSFET. Assuming roughly 90% efficiency at this current level, this gives a P_{MAX} value of:

(3.3V)(10A/0.9)(0.03) = 1.1W per FET

and a required $R_{DS(ON)}$ of:

$$R_{DS(ON)Q1} = \frac{(5V)\bullet(1.1W)}{(3.3V)(10A)^2} = 0.017\Omega$$

$$R_{DS(ON)Q2} = \frac{(5V)\bullet(1.1W)}{(5V-3.3V)(10A)^2} = 0.032\Omega$$

Note that the required $R_{DS(ON)}$ for Q2 is roughly twice that of Q1 in this example. This application might specify a single 0.03Ω device for Q2 and parallel two more of the same devices to form Q1. Note also that while the required $R_{DS(ON)}$ values suggest large MOSFETs, the power dissipation numbers are only 1.1W per device or less; large TO-220 packages and heat sinks are not necessarily required in high efficiency applications. Siliconix Si4410DY or International Rectifier IRF7413 (both in SO-8) or Siliconix SUD50N03-10 (TO-252) or ON Semiconductor MTD20N03HDL (DPAK) are small footprint surface mount devices with $R_{DS(ON)}$ values below 0.03Ω at 5V of V_{GS} that work well in LTC3830 circuits. Using a higher P_{MAX} value in the $R_{DS(ON)}$ calculations generally decreases the MOSFET cost and the circuit efficiency and increases the MOSFET heat sink requirements.

Table 1 highlights a variety of power MOSFETs for use in LTC3830 applications.

Inductor Selection

The inductor is often the largest component in an LTC3830 design and must be chosen carefully. Choose the inductor value and type based on output slew rate requirements. The maximum rate of rise of inductor current is set by the inductor's value, the input-to-output voltage differential and the LTC3830's maximum duty cycle. In a typical 5V input, 3.3V output application, the maximum rise time will be:

$$\frac{DC_{MAX}\bullet(V_{IN}-V_{OUT})}{L_O} = \frac{1.615}{L_O}\ \frac{A}{\mu s}$$

APPLICATIONS INFORMATION

where L_O is the inductor value in μH. With proper frequency compensation, the combination of the inductor and output capacitor values determine the transient recovery time. In general, a smaller value inductor improves transient response at the expense of ripple and inductor core saturation rating. A 2μH inductor has a 0.81A/μs rise time in this application, resulting in a 6.2μs delay in responding to a 5A load current step. During this 6.2μs, the difference between the inductor current and the output current is made up by the output capacitor. This action causes a temporary voltage droop at the output. To minimize this effect, the inductor value should usually be in the 1μH to 5μH range for most 5V input LTC3830 circuits. To optimize performance, different combinations of input and output voltages and expected loads may require different inductor values.

Once the required value is known, the inductor core type can be chosen based on peak current and efficiency requirements. Peak current in the inductor will be equal to the maximum output load current plus half of the peak-to-peak inductor ripple current. Ripple current is set by the inductor value, the input and output voltage and the operating frequency. The ripple current is approximately equal to:

$$I_{RIPPLE} = \frac{(V_{IN} - V_{OUT}) \bullet (V_{OUT})}{f_{OSC} \bullet L_O \bullet V_{IN}}$$

f_{OSC} = LTC3830 oscillator frequency = 200kHz

L_O = Inductor value

Solving this equation with our typical 5V to 3.3V application with a 2μH inductor, we get:

$$\frac{(5V - 3.3V) \bullet 3.3V}{200kHz \bullet 2\mu H \bullet 5V} = 2.8A_{P-P}$$

Peak inductor current at 10A load:

10A + (2.8A/2) = 11.4A

The ripple current should generally be between 10% and 40% of the output current. The inductor must be able to withstand this peak current without saturating, and the copper resistance in the winding should be kept as low as possible to minimize resistive power loss. Note that in circuits not employing the current limit function, the current in the inductor may rise above this maximum under short-circuit or fault conditions; the inductor should be sized accordingly to withstand this additional current. Inductors with gradual saturation characteristics are often the best choice.

Input and Output Capacitors

A typical LTC3830 design places significant demands on both the input and the output capacitors. During normal steady load operation, a buck converter like the LTC3830 draws square waves of current from the input supply at the switching frequency. The peak current value is equal to the output load current plus 1/2 the peak-to-peak ripple current. Most of this current is supplied by the input bypass capacitor. The resulting RMS current flow in the input capacitor heats it and causes premature capacitor failure in extreme cases. Maximum RMS current occurs with 50% PWM duty cycle, giving an RMS current value equal to $I_{OUT}/2$. A low ESR input capacitor with an adequate ripple current rating must be used to ensure reliable operation. Note that capacitor manufacturers' ripple current ratings are often based on only 2000 hours (3 months) lifetime at rated temperature. Further derating of the input capacitor ripple current beyond the manufacturer's specification is recommended to extend the useful life of the circuit. Lower operating temperature has the largest effect on capacitor longevity.

APPLICATIONS INFORMATION

The output capacitor in a buck converter under steady-state conditions sees much less ripple current than the input capacitor. Peak-to-peak current is equal to inductor ripple current, usually 10% to 40% of the total load current. Output capacitor duty places a premium not on power dissipation but on ESR. During an output load transient, the output capacitor must supply all of the additional load current demanded by the load until the LTC3830 adjusts the inductor current to the new value. ESR in the output capacitor results in a step in the output voltage equal to the ESR value multiplied by the change in load current. An 5A load step with a 0.05Ω ESR output capacitor results in a 250mV output voltage shift; this is 7.6% of the output voltage for a 3.3V supply! Because of the strong relationship between output capacitor ESR and output load transient response, choose the output capacitor for ESR, not for capacitance value. A capacitor with suitable ESR will usually have a larger capacitance value than is needed to control steady-state output ripple.

Electrolytic capacitors rated for use in switching power supplies with specified ripple current ratings and ESR can be used effectively in LTC3830 applications. OS-CON electrolytic capacitors from Sanyo and other manufacturers give excellent performance and have a very high performance/size ratio for electrolytic capacitors. Surface mount applications can use either electrolytic or dry tantalum capacitors. Tantalum capacitors must be surge tested and specified for use in switching power supplies. Low cost, generic tantalums are known to have very short lives followed by explosive deaths in switching power supply applications. Other capacitors that can be used include the Sanyo POSCAP and MV-WX series.

A common way to lower ESR and raise ripple current capability is to parallel several capacitors. A typical LTC3830 application might exhibit 5A input ripple current. Sanyo OS-CON capacitors, part number 10SA220M (220µF/10V), feature 2.3A allowable ripple current at 85°C; three in parallel at the input (to withstand the input ripple current) meet the above requirements. Similarly, Sanyo POSCAP 4TPB470M (470µF/4V) capacitors have a maximum rated ESR of 0.04Ω; three in parallel lower the net output capacitor ESR to 0.013Ω.

Feedback Loop Compensation

The LTC3830 voltage feedback loop is compensated at the COMP pin, which is the output node of the error amplifier. The feedback loop is generally compensated with an RC + C network from COMP to GND as shown in Figure 10a.

Loop stability is affected by the values of the inductor, the output capacitor, the output capacitor ESR, the error amplifier transconductance and the error amplifier compensation network. The inductor and the output capacitor create a double pole at the frequency:

$$f_{LC} = 1/\left[2\pi\sqrt{(L_O)(C_{OUT})}\right]$$

The ESR of the output capacitor and the output capacitor value form a zero at the frequency:

$$f_{ESR} = 1/\left[2\pi(ESR)(C_{OUT})\right]$$

The compensation network used with the error amplifier must provide enough phase margin at the 0dB crossover frequency for the overall open-loop transfer function. The zero and pole from the compensation network are:

$f_Z = 1/[2\pi(R_C)(C_C)]$ and

$f_P = 1/[2\pi(R_C)(C1)]$ respectively

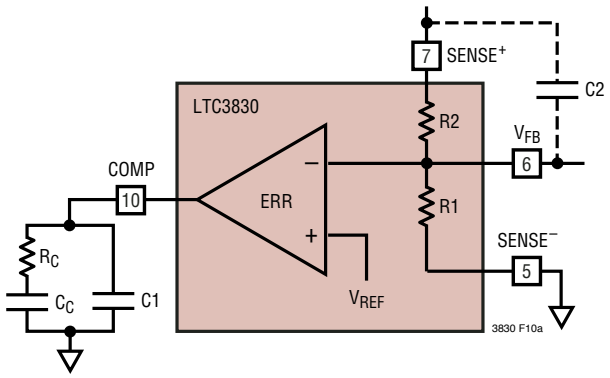

Figure 10a. Compensation Pin Hook-Up

APPLICATIONS INFORMATION

Figure 10b shows the Bode plot of the overall transfer function.

When low ESR output capacitors (Sanyo OS-CON) are used, the ESR zero can be high enough in frequency that it provides little phase boost at the loop crossover frequency. As a result, the phase margin becomes inadequate and the load transient is not optimized. To resolve this problem, a small capacitor can be connected between the top of the resistor divider network and the V_{FB} pin to create a pole-zero pair in the loop compensation. The zero location is prior to the pole location and thus, phase lead can be added to boost the phase margin at the loop crossover frequency. The pole and zero locations are located at:

$f_{ZC2} = 1/[2\pi(R2)(C2)]$ and

$f_{PC2} = 1/[2\pi(R1||R2)(C2)]$

where R1||R2 is the parallel combination resistance of R1 and R2. Choose C2 so that the zero is located at a lower frequency compared to f_{CO} and the pole location is high enough that the closed loop has enough phase margin for stability. Figure 10c shows the Bode plot using phase lead compensation around the LTC3830 resistor divider network. Note: This technique is effective only when R1 >> R2 i.e., at high output voltages only so that the pole and zero are sufficiently separated.

Although a mathematical approach to frequency compensation can be used, the added complication of input and/or output filters, unknown capacitor ESR, and gross operating point changes with input voltage, load current variations, all suggest a more practical empirical method. This can be done by injecting a transient current at the load and using an RC network box to iterate toward the final values, or by obtaining the optimum loop response using a network analyzer to find the actual loop poles and zeros.

LAYOUT CONSIDERATIONS

When laying out the printed circuit board, use the following checklist to ensure proper operation of the LTC3830. These items are also illustrated graphically in the layout diagram of Figure 11. The thicker lines show the high current paths. Note that at 10A current levels or above, current density in the PC board itself is a serious concern. Traces carrying high current should be as wide as possible. For example, a PCB fabricated with 2oz copper requires a minimum trace width of 0.15" to carry 10A.

1. In general, layout should begin with the location of the power devices. Be sure to orient the power circuitry so that a clean power flow path is achieved. Conductor widths should be maximized and lengths minimized. After you are satisfied with the power path, the control circuitry should be laid out. It is much easier to find routes for the relatively small traces in the control circuits than it is to find circuitous routes for high current paths.

2. The GND and PGND pins should be shorted directly at the LTC3830. This helps to minimize internal ground disturbances in the LTC3830 and prevent differences in ground potential from disrupting internal circuit operation. This connection should then tie into the ground plane at a single point, preferably at a fairly quiet point in the circuit such as close to the output capacitors. This is not always practical, however, due to physical constraints. Another reasonably good point to make this connection is between the output capacitors and the source connection of the bottom MOSFET Q2. Do not tie this single point ground in the trace run between the Q2 source and the input capacitor ground, as this area of the ground plane will be very noisy.

APPLICATIONS INFORMATION

3. The small-signal resistors and capacitors for frequency compensation and soft-start should be located very close to their respective pins and the ground ends connected to the signal ground pin through a separate trace. Do not connect these parts to the ground plane!

4. The V_{CC}, PV_{CC1} and PV_{CC2} decoupling capacitors should be as close to the LTC3830 as possible. The 4.7µF and 1µF bypass capacitors shown at V_{CC}, PV_{CC1} and PV_{CC2} will help provide optimum regulation performance.

5. The (+) plate of C_{IN} should be connected as close as possible to the drain of the upper MOSFET, Q1. An additional 1µF ceramic capacitor between V_{IN} and power ground is recommended.

6. The SENSE and V_{FB} pins are very sensitive to pickup from the switching node. Care should be taken to isolate SENSE and V_{FB} from possible capacitive coupling to the inductor switching signal. Connecting the $SENSE^+$ and $SENSE^-$ close to the load can significantly improve load regulation.

7. Kelvin sense I_{MAX} and I_{FB} at Q1's drain and source pins.
