## ISL6413

Triple Output Regulator with Single Synchronous Buck and Dual LDO

FN9129  
Rev 0.00  
Oct 29, 2003

The ISL6413 is a highly integrated triple output regulator which provides a single chip solution for wireless chipset power management. The device integrates high efficiency synchronous buck regulator with two ultra low noise LDO regulators. The IC accepts an input voltage range of 3.0V to 3.6V and provides three regulated output voltages: 1.8V (PWM), 2.84V (LDO1), and another ultra-clean 2.84V (LDO2).

The Synchronous current mode PWM regulator with integrated N- and P-channel power MOSFET provides pre-set 1.8V for BBP/MAC core supply. Synchronous rectification with internal MOSFETs is used to achieve higher efficiency and reduced number of external components. Operating frequency is typically 750kHz allowing the use of smaller inductor and capacitor values. The device can be synchronized to an external clock signal in the range of 500kHz to 1MHz. The PG\_PWM output indicates loss of regulation on PWM output.

The ISL6413 also has two LDO regulators which use an internal PMOS transistor as the pass device. LDO2 features ultra low noise that does not typically exceed 30µV RMS to aid VCO stability. The EN\_LDO pin controls LDO1 and LDO2 outputs. The ISL6413 also integrates a RESET function, which eliminates the need for additional RESET IC required in WLAN applications. The IC asserts a RESET signal whenever the  $V_{IN}$  supply voltage drops below a preset threshold, keeping it asserted for at least 25ms after  $V_{IN}$  has risen above the reset threshold. The PG\_LDO output indicates loss of regulation on either of the two LDO outputs. Other features include over current protection for all three outputs and thermal shutdown.

High integration and the thin Quad Flat No-lead (QFN) package makes ISL6413 an ideal choice to power many of today's small form factor industry standard wireless cards such as PCMCIA, mini-PCI and Cardbus-32.

### Ordering Information

PART NUMBER	TEMP. RANGE (°C)	PACKAGE	PKG. DWG. #
ISL6413IR	-40 to 85	24 Ld QFN	L24.4x4B

### Features

- Fully Integrated Synchronous Buck Regulator + Dual LDO
- High Output Current (For QFN package)
  - PWM, 1.8V . . . . . 400mA
  - LDO1, 2.84V . . . . . 300mA
  - LDO2, 2.84V . . . . . 200mA
- Ultra-Compact DC-DC Converter Design
- Stable with Small Ceramic Output Capacitors
- High conversion efficiency
- Low Shutdown supply current
- Ultra-Low Dropout Voltage for LDOs
  - LDO1, 2.84V . . . . . 125mV (typ.) at 300mA
  - LDO2, 2.84V . . . . . 100mV (typ.) at 200mA
- Ultra-Low Output Voltage Noise
  - <30µV<sub>RMS</sub> (typ.) for LDO2 (VCO Supply)
- PG\_LDO, PG\_PWM and  $\overline{\text{PG\_PWM}}$  outputs
- Extensive circuit protection and monitoring features
  - Over voltage protection
  - Over current protection
  - Shutdown
  - Thermal Shutdown
- Integrated RESET output for microprocessor reset
- Proven Reference Design for Total WLAN System Solution
- QFN Package
  - Compliant to JEDEC PUB95 MO-220 QFN - Quad Flat No Leads - Product Outline
  - Near Chip-Scale Package Footprint Improves PCB Efficiency and Is Thinner in Profile

### Applications

- WLAN Cards
  - PCMCIA, Cardbus32, MiniPCI Cards
  - Compact Flash Cards
- Liberty Chipset
- Hand-Held Instruments

NOTE:

- Specifications at  $-40^{\circ}C$  and  $+85^{\circ}C$  are guaranteed by design/characterization, not production tested.
- This is the  $V_{IN}$  current consumed when the device is active but not switching. Does not include gate drive current.
- The dropout voltage is defined as  $V_{IN} - V_{OUT}$ , when  $V_{OUT}$  is 50mV below the value of  $V_{OUT}$  for  $V_{IN} = V_{OUT} + 0.5V$ .
- The RESET timeout period is linear with CT at the slope of 2.5ms/nF. Thus, at 10nF (0.01 $\mu F$ ) the RESET time is 25ms; at 1000nF (0.1 $\mu F$ ) the RESET time would be 250ms.
- Guaranteed by design, not production tested.

## Pin Descriptions

**PVCC** - Positive supply for the power (internal FET) stage of the PWM section.

**SGND** - Analog ground for the PWM. All internal control circuits are referenced to this pin.

**EN\_PWM** - The PWM controller is enabled when this pin is HIGH, and held off when the pin is pulled LOW. It is a CMOS logic-level input (referenced to  $V_{IN}$ ).

**$V_{IN\_LDO}$**  - This is the input voltage pin for LDO1 and LDO2.

**EN\_LDO** - LDO1 and LDO2 are enabled when this pin is HIGH, and held off when the pin is pulled LOW. It is a CMOS logic-level input (referenced to  $V_{IN}$ ).

**CT** - Timing capacitor connection to set the 25ms minimum pulse width for the RESET/RESET signal.

**RESET,  $\overline{\text{RESET}}$**  - These complementary pins are the outputs of the reset supervisory circuit, which monitors  $V_{IN}$ . The IC asserts these RESET and  $\overline{\text{RESET}}$  signals whenever the supply voltage drops below a preset threshold; keeping them asserted for at least 25ms after  $V_{CC}$  ( $V_{IN}$ ) has risen above the reset threshold. These outputs are push-pull. RESET is LOW when re-setting the microprocessor. The device will continue to operate until  $V_{IN}$  drops below the UVLO threshold.

**PG\_LDO** - This is a high impedance open drain output that provides the status of both LDOs. When either of the outputs are out of regulation, PG\_LDO goes LOW.

**CC1** - This is the compensation capacitor connection for LDO1. Connect a 0.033 $\mu$ F capacitor from CC1 to GND\_LDO.

**CC2** - This is the compensation capacitor connection for LDO2. Connect a 0.033 $\mu$ F capacitor from CC2 to GND\_LDO.

**$V_{OUT2}$**  - This pin is the output of LDO2. Bypass with a 2.2 $\mu$ F, low ESR capacitor to GND\_LDO for stable operation.

**GND\_LDO** - Ground pin for LDO1 and LDO2.

**$V_{OUT1}$**  - This pin is the output of LDO1. Bypass with a 2.2 $\mu$ F, low ESR capacitor to GND\_LDO for stable operation.

**PGND** - Power ground for the PWM controller stage.

**$V_{OUT}$**  - This I/O pin senses the output voltage of the PWM converter stage. For fixed 1.8V operation, connect this pin directly to the output voltage.

**PG\_PWM** - This pin is an active pull-up/pull-down able to source/sink 1mA (min.) at 0.4V from  $V_{IN}/SGND$ . This output is HIGH when  $V_{OUT}$  is within  $\pm 8\%$  (typ.).

**$\overline{\text{PG\_PWM}}$**  - This pin provides an inverted PG\_PWM output.

**LX** - The LX pin is the switching node of synchronous buck converter, connected internally at the junction point of the upper MOSFET source and lower MOSFET drain. Connect this pin to the output inductor.

**$V_{IN}$**  - This pin is the power supply for the PWM controller stage and must be closely decoupled to ground.

**SYNC** - This is the external clock synchronization input. The device can be synchronized to 500kHz to 1MHz switching frequency.

**GND** - Tie this pin to the ground plane with a low impedance, shortest possible path.

## Functional Description

The ISL6413 is a 3-in-1 multi-output regulator designed for wireless chipset power applications. The device integrates a single synchronous buck regulator with dual LDOs. It supplies three fixed output voltages 1.8V, 2.84V and 2.84V. The 1.8V is generated using a synchronous buck regulator with greater than 92% efficiency. Both 2.84V supplies are generated from ultra low noise LDO Regulators. Under voltage lock-out (UVLO) prevents the converter from turning on when the input voltage is less than typically 2.6V

Additional blocks include an output over-current protections, thermal sensor, PGOOD detectors, RESET function and shutdown logic.

### Synchronous Buck Regulator

The Synchronous buck regulator with integrated N- and P-channel power MOSFET provides pre-set 1.8V for BBP/MAC core supply. Synchronous rectification with internal MOSFETs is used to achieve higher efficiency and reduced number of external components. Operating frequency is typically 750kHz allowing the use of smaller inductor and capacitor values. The device can be synchronized to an external clock signal in the range of 500kHz to 1MHz. The PG\_PWM output indicates loss of regulation on PWM output.

The PWM architecture uses a peak current mode control scheme with internal slope compensation. At the beginning of each clock cycle, the high side P-channel MOSFET is turned on. The current in the inductor ramps up and is sensed via an internal circuit. The error amplifier sets the threshold for the PWM comparator. The high side switch is turned off when the sensed inductor current reaches this threshold. After a minimum dead time preventing shoot through current, the low side N-channel MOSFET will be turned on and the current ramps down again. As the clock cycle is completed, the low side switch will be turned off and the next clock cycle starts.

The control loop is internally compensated reducing the amount of external components. The PWM section includes an anti-ringing switch to reduce noise at light loads.

The switch current is internally sensed and the minimum current limit is 600mA.

### Synchronization

The typical operating frequency for the converter is 750kHz if no clock signal is applied to SYNC pin. It is possible to synchronize the converter to an external clock within a

frequency range from 500kHz to 1000kHz. The device automatically detects the rising edge of the first clock and will synchronize immediately to the external clock. If the clock signal is stopped, the converter automatically switches back to the internal clock and continues operation without interruption. The switch over will be initiated if no rising edge on the SYNC pin is detected for a duration of two internal 1.3 $\mu$ s clock cycles.

### Soft Start

As the EN\_PWM (Enable) pin goes high, the soft-start function will generate an internal voltage ramp. This causes the start-up current to slowly rise preventing output voltage overshoot and high inrush currents. The soft-start duration is typically 5.5ms with 750kHz switching frequency. When the soft-start is completed, the error amplifier will be connected directly to the internal voltage reference. The SYNC input is ignored during soft start.

### Enable PWM

Logic low on EN\_PWM pin forces the PWM section into shutdown. In shutdown all the major blocks of the PWM including power switches, drivers, voltage reference, and oscillator are turned off.

### Power Good (PG\_PWM)

When chip is enabled, this output is HIGH, when  $V_{OUT}$  is within 8% of 1.8V and active low outside this range. When the PWM is disabled, the output is active low.  $\overline{PG\_PWM}$  is the complement of PG\_PWM.

Leave the PG\_PWM pin unconnected when not used.

### PWM Overvoltage and Overcurrent Protection

The PWM output current is sampled at the end of each PWM cycle. Should it exceed the overcurrent limit, a 4 bit up/down counter counts up two LSB. Should it not be in overcurrent the counter counts down one LSB (but counter will not "rollover" or count below 0000). If >33% of the PWM cycles go into overcurrent, the counter rapidly reaches count 1111 and the PWM output is shut down and the softstart counter is reset. After 16 clocks the PWM output is enabled and the SS cycle is started.

If  $V_{OUT}$  exceeds the overvoltage limit for 32 consecutive clock cycles the PWM output is shut off and the SS counters reset. The softstart cycle will not be started until EN or  $V_{IN}$  are toggled.

### PG\_LDO

PG\_LDO is an open drain pulldown NMOS output that will sink 1mA at 0.4V max. It goes to the active low state if either LDO output is out of regulation by more than 15%. When the LDO is disabled, the output is active low.

### LDO Regulators

Each LDO consists of a 1.184V reference, error amplifier, MOSFET driver, P-Channel pass transistor, dual-mode comparator and internal feedback voltage divider.

The 1.2V band gap reference is connected to the error amplifier's inverting input. The error amplifier compares this reference to the selected feedback voltage and amplifies the difference. The MOSFET driver reads the error signal and applies the appropriate drive to the P-Channel pass transistor. If the feedback voltage is lower than the reference voltage, the pass transistor gate is pulled lower, allowing more current to pass and increasing the output voltage. If the feedback voltage is higher than the reference voltage, the pass transistor gate is driven higher, allowing less current to pass to the output. The output voltage is fed back through an internal resistor divider connected to  $V_{OUT1}/V_{OUT2}$  pins.

### Internal P-Channel Pass Transistors

The ISL6413 LDO Regulators features a typical 0.5 $\Omega$   $R_{ds(ON)}$  P-channel MOSFET pass transistors. This provides several advantages over similar designs using PNP bipolar pass transistors. The P-Channel MOSFET requires no base drive, which reduces quiescent current considerably. PNP based regulators waste considerable current in dropout when the pass transistor saturates. They also use high base drive currents under large loads. The ISL6413 does not suffer from these problems.

### Integrated RESET for MAC/ Baseband Processors

The ISL6413 includes a microprocessor supervisory block. This block eliminates the extra RESET IC and external components needed in wireless chipset applications. This block performs a single function; it asserts a RESET signal whenever the  $V_{IN}$  supply voltage decreases below a preset threshold, keeping it asserted for a programmable time (set by external capacitor CT) after the  $V_{IN}$  pin voltage has risen above the RESET threshold.

The push pull output stage of the reset circuit provides both an active-Low and an active-HIGH output. The RESET threshold for ISL6413 is 2.630V typical.

UVLO Reset threshold is always lower than RESET. This insures that as  $V_{IN}$  falls, reset goes low before LDOs and PWM are shuts off.

### Output Voltages

The ISL6413 provides fixed output voltages for use in Wireless Chipset applications. Internal trimmed resistor networks set the typical output voltages as shown here:

$$V_{OUT\_PWM} = 1.8V; V_{OUT1} = 2.84V; V_{OUT2} = 2.84V.$$

### Integrator Circuitry

The ISL6413 LDO Regulators uses an external 33nF compensation capacitor for minimizing load and line regulation errors and for lowering output noise. When the output voltage shifts due to varying load current or input voltage, the integrator capacitor voltage is raised or lowered to compensate for the systematic offset at the error amplifier. Compensation is limited to  $\pm 5\%$  to minimize transient overshoot when the device goes out of dropout, current limit, or thermal shutdown.

### Shutdown

Driving the EN\_LDO pin low will put LDO1 and LDO2 into the shutdown mode. Driving the EN\_PWM pin low will put the PWM into shutdown mode. Pulling the EN\_PWM and EN\_LDO both pins low simultaneously, puts the complete chip into shutdown mode, and supply current drops to 15µA typical.

### Protection Features for the LDOs

#### Current Limit

The ISL6413 monitors and controls the pass transistor's gate voltage to limit the output current. The current limit for LDO1 is 330mA and LDO2 is 250mA. The output can be shorted to ground without damaging the part due to the current limit and thermal protection features.

#### Thermal Overload Protection

Thermal overload protection limits total power dissipation in the ISL6413. When the junction temperature ( $T_J$ ) exceeds +150°C, the thermal sensor sends a signal to the shutdown logic, turning off the pass transistor and allowing the IC to cool. The pass transistor turns on again after the IC's junction temperature typically cools by 20°C, resulting in a pulsed output during continuous thermal overload conditions. Thermal overload protection protects the ISL6413 against fault conditions. For continuous operation, do not exceed the absolute maximum junction temperature rating of +150°C.

#### Operating Region and Power Dissipation

The maximum power dissipation of ISL6413 depends on the thermal resistance of the IC package and circuit board, the temperature difference between the die junction and ambient air, and the rate of air flow. The power dissipated in the device is:

$$P_T = P_1 + P_2 + P_3, \text{ where}$$

$$P_1 = I_{OUT1} \times V_{OUT1} / I_{IN} \times V_{IN}$$

$$P_2 = I_{OUT2} (V_{IN} - V_{OUT2})$$

$$P_3 = I_{OUT3} (V_{IN} - V_{OUT3})$$

The maximum power dissipation is:

$$P_{max} = (T_{jmax} - T_A) / \theta_{JA}$$

Where  $T_{jmax} = 150^\circ\text{C}$ ,  $T_A$  = ambient temperature, and  $\theta_{JA}$  is the thermal resistance from the junction to the surrounding environment.

The ISL6413 package features an exposed thermal pad on its underside. This pad lowers the thermal resistance of the package by providing a direct heat conduction path from the die to the PC board. Additionally, the ISL6413's ground (GND\_LDO and PGND) performs the dual function of providing an electrical connection to system ground and channeling heat away. Connect the exposed backside pad direct to the GND\_LDO ground plane.

## Applications Information

### LDO Regulator Capacitor Selection and Regulator Stability

Capacitors are required at the ISL6413 LDO Regulators' input and output for stable operation over the entire load range and the full temperature range. Use >1µF capacitor at the input of LDO Regulators,  $V_{IN\_LDO}$  pins. The input capacitor lowers the source impedance of the input supply. Larger capacitor values and lower ESR provides better PSRR and line transient response. The input capacitor must be located at a distance of not more than 0.5 inches from the  $V_{IN}$  pins of the IC and returned to a clean analog ground. Any good quality ceramic capacitor can be used as an input capacitor.

The output capacitor must meet the requirements of minimum amount of capacitance and ESR for both LDO's. The ISL6413 is specifically designed to work with small ceramic output capacitors. The output capacitor's ESR affects stability and output noise. Use an output capacitor with an ESR of 50mΩ or less to insure stability and optimum transient response. For stable operation, a ceramic capacitor, with a minimum value of 3.3µF, is recommended for  $V_{OUT1}$  for 300mA output current, and 3.3µF is recommended for  $V_{OUT2}$  at 200mA load current. There is no upper limit to the output capacitor value. Larger capacitor can reduce noise and improve load transient response, stability and PSRR. Higher value of output capacitor (10µF) is recommended for LDO2 when used to power VCO circuitry in wireless chipsets. The output capacitor should be located very close to  $V_{OUT}$  pins to minimize impact of PC board inductances and the other end of the capacitor should be returned to a clean analog ground.

### PWM Regulator Component Selection

#### INDUCTOR SELECTION

A 10µH minimum output inductor is used with the ISL6413 PWM section. Values larger than 15µH or less than 10µH may cause stability problems because of the internal compensation of the regulator. The important parameters of the inductor that need to be considered are the current rating of the inductor and the DC resistance of the inductor. The dc resistance of the inductor will influence directly the efficiency of the converter. Therefore, an inductor with lowest dc resistance should be selected for highest efficiency.

In order to avoid saturation of the inductor, the inductor should be rated at least for the maximum output current plus the inductor ripple current.

**TABLE 1. RECOMMENDED INDUCTORS**

OUTPUT CURRENT	INDUCTOR VALUE	VENDOR PART #	COMMENTS

### OUTPUT CAPACITOR SELECTION

For best performance, a low ESR output capacitor is needed. If an output capacitor is selected with an ESR value  $\leq 120\text{m}\Omega$ , its RMS ripple current will always meet the application requirements. The RMS ripple current is calculated as:

$$I_{\text{RMS}(C)_O} = V_O \times \frac{1 - \frac{V_O}{V_I}}{L \times f} \times \frac{1}{2 \times \sqrt{3}}$$

The overall output ripple voltage is the sum of the voltage spike caused by the output capacitor ESR plus the voltage ripple caused by charge and discharging the output capacitor:

$$\Delta V_O = V_O \times \left( \frac{1 - \frac{V_O}{V_I}}{L \times f} \right) \times \left( \frac{1}{8 \times C_O \times f} + \text{ESR} \right)$$

Where the highest output voltage ripple occurs at the highest input voltage  $V_I$ .

**TABLE 2. RECOMMENDED CAPACITORS**

CAPACITOR VALUE	ESR/mΩ	VENDOR PART #	COMMENTS
10μF	50	Taiyo Yuden JMK316BJ106KL	Ceramic
47μF	100	Sanyo 6TPA47M	POSCAP
68μF	100	Sprague 594D686X0010C2T	Tantalum

### INPUT CAPACITOR SELECTION

Because of the nature of the buck converter having a pulsating input current, a low ESR input capacitor is required for best input voltage filtering and minimizing the interference with other circuits caused by high input voltage spikes.

The input capacitor should have a minimum value of 10μF and can be increased without any limit for better input voltage filtering. The input capacitor should be rated for the maximum input ripple current calculated as:

$$I_{\text{RMS}} = I_{O(\text{max})} \times \sqrt{\frac{V_O}{V_I} \times \left( 1 - \frac{V_O}{V_I} \right)}$$

The worst case RMS ripple current occurs at  $D = 0.5$ .

Ceramic capacitors show good performance because of their low ESR value, and because they are less sensitive to voltage transients, compared to tantalum capacitors.

Place the input capacitor as close as possible to the input pin of the IC for best performance.

**Layout Considerations**

As for all switching power supplies, the layout is an important step in the design especially at high peak currents and switching frequencies. If the layout is not carefully done, the regulator might show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current paths. The input capacitor should be placed as close as possible to the IC pins as well as the inductor and output capacitor. Use a common ground node to minimize the effects of ground noise.

Allocate two board levels as ground planes, with many vias between them to create a low impedance, high-frequency plane. Tie all the device ground pins through multiple vias each to this ground plane, as close to the device as possible. Also tie the exposed pad on the bottom of the device to this ground plane.

Refer to application note AN1081.

**NOTES:**

1. Dimensioning and tolerancing conform to ASME Y14.5-1994.
2. N is the number of terminals.
3. Nd and Ne refer to the number of terminals on each D and E.
4. All dimensions are in millimeters. Angles are in degrees.
5. Dimension b applies to the metallized terminal and is measured between 0.15mm and 0.30mm from the terminal tip.
6. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.
7. Dimensions D2 and E2 are for the exposed pads which provide improved electrical and thermal performance.
8. Nominal dimensions are provided to assist with PCB Land Pattern Design efforts, see Intersil Technical Brief TB389.
9. Features and dimensions A2, A3, D1, E1, P & θ are present when Anvil singulation method is used and not present for saw singulation.
10. Depending on the method of lead termination at the edge of the package, a maximum 0.15mm pull back (L1) maybe present. L minus L1 to be equal to or greater than 0.3mm.
