

**THE DATASHEET OF  
MX7824KCWG+**

# CMOS, High-Speed, 8-Bit ADCs with Multiplexer

MX7824/MX7828

## General Description

The MAX154/MAX158 and MX7824/MX7828 are high-speed, multi-channel analog-to-digital converters (ADCs). The MAX154 and MX7824 have four analog input channels, while the MAX158 and MX7828 have eight channels. Conversion time for all devices is 2.5µs. The MAX154/MAX158 also feature a 2.5V on-chip reference, forming a complete high-speed data acquisition system.

All four converters include a built-in track/hold, eliminating the need for an external track/hold with many input signals. The analog input range is 0V to +5V, although the ADC operates from a single +5V supply.

Microprocessor interfaces are simplified by the ADC's ability to appear as a memory location or I/O port without the need for external logic. The data outputs use latched, three-state buffer circuitry to allow direct connection to a microprocessor data bus or system input port.

The MX7824 and MX7828 are pin compatible with Analog Devices' AD7824 and AD7828. The MAX154 and MAX158, which feature internal references, are also compatible with these products.

## Applications

- Digital Signal Processing
- High-Speed Data Acquisition
- Telecommunications
- High-Speed Servo Control
- Audio Instrumentation

## Features

- ♦ One-Chip Data Acquisition System
- ♦ Four or Eight Analog Input Channels
- ♦ 2.5µs per Channel Conversion Time
- ♦ Internal 2.5V Reference (MAX154/MAX158 only)
- ♦ Built-In Track/Hold Function
- ♦ 1/2LSB Error Specification
- ♦ Single +5V Supply Operation
- ♦ No External Clock
- ♦ New Space-Saving SSOP Package

## Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE	ERROR (LSB)
MX7824LN	0°C to +70°C	24 Narrow Plastic DIP	±1/2
MX7824KN	0°C to +70°C	24 Narrow Plastic DIP	±1
MX7824LCWG	0°C to +70°C	24 Wide SO	±1/2
MX7824KCWG	0°C to +70°C	24 Wide SO	±1
MX7824LCAG	0°C to +70°C	24 SSOP	±1/2
MX7824KCAG	0°C to +70°C	24 SSOP	±1

## Pin Configurations

# CMOS, High-Speed, 8-Bit ADCs with Multiplexer

## ABSOLUTE MAXIMUM RATINGS

Supply Voltage, V<sub>DD</sub> to GND .....0V, +10V  
 Voltage at Any Other Pins .....GND - 0.3V, V<sub>DD</sub> + 0.3V  
 Output Current (REF OUT) .....30mA  
 Power Dissipation (any package) to +75°C .....450mW  
 Derate above +25°C by .....6mW/°C

### Operating Temperature Ranges

MX7824, MX7828  
 KN/LN/KCW/LCW\_ .....0°C to +70°C  
 BO/CO .....-40°C to +85°C  
 TQ/UQ .....-55°C to +125°C  
 Storage Temperature Range .....-65°C to +160°C  
 Lead Temperature (soldering, 10sec) .....+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

# CMOS, High-Speed, 8-Bit ADCs with Multiplexer

## Detailed Description

### Converter Operation

The MAX154/MAX158 and MX7824/MX7828 use what is commonly called a "half-flash" conversion technique (Figure 3). Two 4-bit flash ADC sections are used to achieve an 8-bit result. Using 15 comparators, the upper 4-bit MS (most significant) flash ADC compares the unknown input voltage to the reference ladder and provides the upper four data bits.

An internal DAC uses the MS bits to generate an analog signal from the first flash conversion. A residue voltage representing the difference between the unknown input and the DAC voltage is then compared to the reference ladder by 15 LS (least significant) flash comparators to obtain the lower four output bits.

### Operating Sequence

The operating sequence is shown in Figure 4. A conversion is initiated by a falling edge of  $\overline{RD}$  and  $\overline{CS}$ . The comparator inputs track the analog input voltage for approximately 1 $\mu$ s. After this first cycle, the MS flash result is latched into the output buffers and the LS conversion begins.  $\overline{INT}$  goes low approximately 600ns later, indicating the end of the conversion, and that the lower four bits are latched into the output buffers. The data can then be accessed using the  $\overline{CS}$  and  $\overline{RD}$  inputs.

## Digital Interface

The MAX154/MAX158 and MX7824/MX7828 use only Chip Select ( $\overline{CS}$ ) and Read ( $\overline{RD}$ ) as control inputs. A READ operation, taking  $\overline{CS}$  and  $\overline{RD}$  low, latches the multiplexer address inputs and starts a conversion (Table 1).

**Table 1. Truth Table for Input Channel Selection**

MAX154/MX7824		MAX158/MX7828			SELECTED CHANNEL
A1	A0	A2	A1	A0	
0	0	0	0	0	AIN1
0	1	0	0	1	AIN2
1	0	0	1	0	AIN3
1	1	0	1	1	AIN4
		1	0	0	AIN5
		1	0	1	AIN6
		1	1	0	AIN7
		1	1	1	AIN8

There are two interface modes, which are determined by the length of the  $\overline{RD}$  input. Mode 0, implemented by keeping  $\overline{RD}$  low until the conversion ends, is designed for microprocessors that can be forced into a WAIT state. In this mode, a conversion is started with a READ operation (taking  $\overline{CS}$  and  $\overline{RD}$  low), and data is read when the conversion ends. Mode 1, on the other hand,

Figure 3. Functional Diagram

# CMOS, High-Speed, 8-Bit ADCs with Multiplexer

MX7824/MX7828

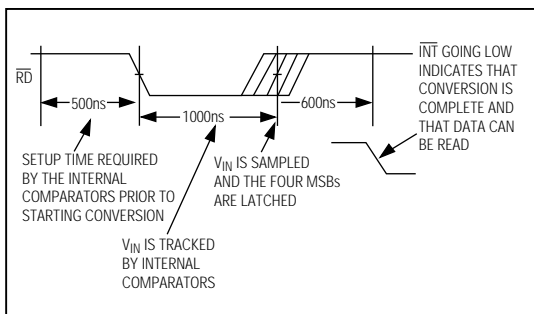

Figure 4. Operating Sequence

does not require microprocessor WAIT states. A READ operation simultaneously initiates a conversion and reads the previous conversion result.

### Interface Mode 0

Figure 5 shows the timing diagram for Mode 0 operation. This is used with microprocessors that have WAIT state capability, whereby a READ instruction is extended to accommodate slow-memory devices. Taking  $\overline{CS}$  and  $\overline{RD}$  low latches the analog multiplexer address and starts a conversion. Data outputs DB0–DB7 remain in the high-impedance condition until the conversion is complete.

Figure 5. Mode 0 Timing Diagram

There are two status outputs: Interrupt ( $\overline{INT}$ ) and Ready (RDY). RDY, an open-drain output (no internal pull-up device), is connected to the processor's READY/WAIT input. RDY goes low on the falling edge of  $\overline{CS}$  and goes high impedance at the end of the conversion, when the conversion result appears on the data outputs. If the RDY output is not required, its external pull-up resistor can be omitted.  $\overline{INT}$  goes low when the conversion is complete and returns high on the rising edge of  $\overline{CS}$  or RD.

### Interface Mode 1

Mode 1 is designed for applications where the microprocessor is not forced into a WAIT state. Taking  $\overline{CS}$  and  $\overline{RD}$  low latches the multiplexer address and starts a conversion (Figure 6). Data from the previous conversion is immediately read from the outputs (DB0–DB7).

$\overline{INT}$  goes high at the rising edge of  $\overline{CS}$  or  $\overline{RD}$  and goes low at the end of the conversion. A second READ operation is required to read the result of this conversion. The second READ latches a new multiplexer address and starts another conversion. A delay of 2.5 $\mu$ s must be allowed between READ operations. RDY goes low on the falling edge of  $\overline{CS}$  and goes high impedance at the rising edge of  $\overline{CS}$ . If RDY is not needed, its external pull-up resistor can be omitted.

## CMOS, High-Speed, 8-Bit ADCs with Multiplexer

Figure 6. Mode 1 Timing Diagram

### Analog Considerations

#### Reference and Input

The  $V_{REF+}$  and  $V_{REF-}$  inputs of the converter define the zero and the full-scale of the ADC. In other words, the voltage at  $V_{REF-}$  is equal to the input voltage that produces an output code of all zeros, and the voltage at  $V_{REF+}$  is equal to input voltage that produces an output code of all ones (Figure 7).

Figure 8 shows some possible reference configurations. For the MAX154/MAX158, a  $0.01\mu\text{F}$  bypass capacitor to GND should be used to reduce the high-frequency output impedance of the internal reference. Larger capacitors should not be used, as this degrades the stability of the reference buffer. The 2.5V reference output is with respect to the GND pin.

#### Bypassing

A  $47\mu\text{F}$  electrolytic and  $0.1\mu\text{F}$  ceramic capacitor should be used to bypass the  $V_{DD}$  pin to GND. These capacitors must have minimum lead length, since excess lead length may contribute to conversion errors and instability. If the reference inputs are driven by long lines, they should be bypassed to GND with  $0.1\mu\text{F}$  capacitors at the reference input pins.

### Input Current

The converters' analog inputs behave somewhat differently from conventional ADCs. The sampled data comparators take varying amounts of current from the input, depending on the cycle they are in. The equivalent circuit of the converter is shown in Figure 9a. When the conversion starts, AIN(n) is connected to the MS and LS comparators. Thus, AIN(n) is connected to thirty-one 1pF capacitors.

To acquire the input signal in approximately 1µs, the input capacitors must charge to the input voltage through the on-resistance of the multiplexer (about 600Ω) and the comparator's analog switches (2kΩ to 5kΩ per comparator). In addition, about 12pF of stray capacitance must be charged. The input can be modeled as an equivalent RC network shown in Figure 9b. As  $R_S$  (source impedance) increases, the capacitors take longer to charge.

Since the length of the input acquisition time is internally set, large source resistances (greater than 100Ω) will cause settling errors. The output impedance of an op-amp is its open-loop output impedance divided by the loop gain at the frequency of interest. It is important that the amplifier driving the converter input have sufficient loop gain at approximately 1MHz to maintain low output impedance.

### Input Filtering

The transients in the analog input caused by the sampled data comparators do not degrade the converter's performance, since the ADC does not "look" at the input when these transients occur. The comparator's outputs track the input during the first 1µs of the conversion, and are then latched. Therefore, at least 1µs will be provided to charge the ADC's input capacitance. It is not necessary to filter these transients with an external capacitor on the AIN terminals.

### Sinusoidal Inputs

The MAX154/MAX158 and MX7824/MX7828 can measure input signals with slew rates as high as 157mV/µs to the rated specifications. This means that the analog input frequency can be as high as 10kHz without the aid of an external track/hold. The maximum sampling rate is limited by the conversion time (typical  $t_{CRD} = 2\mu s$ ) plus the time required between conversions ( $t_p = 500ns$ ). It is calculated as:

$$f_{MAX} = \frac{1}{t_{CRD} + t_p} = \frac{1}{(2.0 + 0.5) \mu s} = 400kHz$$

## CMOS, High-Speed, 8-Bit ADCs with Multiplexer

$f_{MAX}$  permits a maximum sampling rate of 50kHz per channel when using the MAX158/MX7828 and 100kHz per channel when using the MAX154/MX7824. These rates are well above the Nyquist requirement of 20kHz sampling rate for a 10kHz input bandwidth.

### Bipolar Input Operation

The circuit in Figure 10a can be used for bipolar input operation. The input voltage is scaled by an amplifier so that only positive voltages appear at the ADC's inputs. An external reference should be used for the MX7824/MX7828, but is not needed with the MAX154/MAX158. The analog input range is  $\pm 4V$  and the output code is complementary offset binary. The ideal input/output characteristic is shown in Figure 10b.
