73S1210F-44M/F/PC

73S1210F
Self-Contained Smart Card Reader with PINpad and Power Management

Simplifying System Integration™

DATA SHEET

May 2009

GENERAL DESCRIPTION

The 73S1210F is a versatile and economical CMOS System-on-Chip device intended for smart card reader applications. The circuit is built around an 80515 high-performance core; it features primarily an ISO-7816 / EMV interface and a generic asynchronous serial interface. Delivered with turnkey Teridian embedded firmware, it forms a ready-to-use smart card reader solution that can be seamlessly incorporated into any microprocessor-based system where a serial line is available.

The solution is scalable, thanks to a built-in I^2C interface that allows to drive external electrical smart card interfaces such as Teridian 73S8010 ICs. This makes the solution immediately able to support multi-card slots or multi-SAM architectures.

In addition, the 73S1210 features a 5x6 PINpad interface, 8 user I/Os, multiple interrupt options and an analog voltage input (for DC voltage monitoring such as battery level detection) that make it suitable for low-cost PINpad reader devices.

The 80515 CPU core instruction set is compatible with the industry standard 8051, while offering one clock-cycle per instruction processing power (most instructions). With a CPU clock running up to 24MHz, it results in up to 24MIPS available that meets the requirements of various encryption needs such as AES, DES / 3-DES and even RSA (for PIN encryption for instance).

The circuit requires a single 6MHz to 12MHz crystal.

The respective 73S1210F embedded memories are 32KB Flash program memory, 2KB user XRAM memory, and 256B IRAM memory. Dedicated FIFOs for the ISO 7816 UART are independent from the user XRAM and IRAM.

Alternatively to the turnkey firmware offered by Teridian, customers can develop their own embedded firmware directly within their application or using Teridian 73S1210F Evaluation Board through a JTAG-like interface.

The chip incorporates an inductor-based DC-DC converter that generates all the necessary voltages to the various 73S1210F function blocks (smart card interface, digital core, etc.) from any of two distinct power supply sources: the +5V bus (V_{BUS}, 4.4 to 6.5V), or a main battery (V_{BAT}, 4.0V to 6.5V). The chip automatically powers-up the DC-DC converter with V_{BUS} if it is present, or uses V_{BAT} as the supply input if V_{BUS} is not present. Alternatively, the pin V_{PC} can support a wider power supply input range (2.7V to 6.5V), when using a single system supply source.

In addition, the circuit features an ON/OFF mode which operates directly with an ON/OFF system switch: Any activity on the ON/OFF button is debounced internally and controls the power generation circuit accordingly, under the supervision of the firmware (OFF request / OFF acknowledgement at firmware level). The OFF mode can be alternatively initiated from the controller (firmware action instead of ON/OFF switch).

In OFF mode, the circuit typically draws less than 1μA, which makes it ideal for applications where battery life must be maximized.

Embedded Flash memory is in-system programmable and lockable by means of on-silicon fuses. This makes the 73S1210F suitable for both development and production phases.

Teridian Semiconductor Corporation offers with its 73S1210F a very comprehensive set of software libraries for EMV. Refer to the *73S12xxF Software User's Guide* for a complete description of the Application Programming Interface (API Libraries) and related software modules.

A complete array of development and programming tools, libraries and demonstration boards enable rapid development and certification of readers that meet most demanding smart card standards.

APPLICATIONS

- PINpad smart card readers:
  - With serial connectivity
  - Ideal for low-cost POS Terminals and Digital Identification (Secure Login, Gov't ID, ...)
- SIM Readers in Personal Wireless devices
- Payphones & Vending machines
- General purpose smart card readers

ADVANTAGES

- Reduced BOM
- Versatile power supply options
  - 2.7V to 6.5V ranges
- Higher performance CPU core (up to 24MIPS)
- Built-in EMV/ISO slot, expandable to multi-slots
- Flexible power supply options
  - On-chip DC-DC converter
  - CMOS switches between supply inputs
- Sub-μA Power Down mode with ON/OFF switch
- Powerful In-Circuit Emulation and Programming
- A complete set of EMV4.1 / ISO7816 libraries
- Turnkey PC/SC firmware and host drivers
  - Multiple OS supported

FEATURES

80515 Core:

- 1 clock cycle per instruction (most instructions)
- CPU clocked up to 24MHz
- 32KB Flash memory (lockable)
- 2kB XRAM (User Data Memory)
- 256 byte IRAM
- Hardware watchdog timer

Oscillators:

- Single low-cost 6MHz to 12MHz crystal
- An Internal PLL provides all the necessary clocks to each block of the system

Interrupts:

- Standard 80C515 4-priority level structure
- 9 different sources of interrupt to the core

Power Down Modes:

- 2 standard 80C515 Power Down and IDLE modes
- Sub-μA OFF mode
- ON/OFF Main System Power Switch:
- Input for an SPST momentary switch to ground

Timers:

- (2) Standard 80C52 timers T0 and T1
- (1) 16-bit timer

Built-in ISO-7816 Card Interface:

- Linear regulator produces VCC for the card (1.8V, 3V or 5V)
- Full compliance with EMV 4.1
- Activation/Deactivation sequencers
- Auxiliary I/O lines (C4 and C8 signals)
- 7kV ESD protection on all interface pins

Communication with Smart Cards:

- ISO 7816 UART 9600 to 115kbps for T=0, T=1
- (2) 2-Byte FIFOs for transmit and receive
- Configured to drive multiple external Teridian 73S8010x interfaces (for multi-SAM architectures)

Voltage Detection:

- Analog Input (detection range: 1.0V to 2.5V)

Communication Interfaces:

- Full-duplex serial interface (1200 to 115kbps UART)
- I^2C Master Interface (400kbps)
- Man-Machine Interface and I/Os:
- 6x5 Keyboard (hardware scanning, debouncing and scrambling)
- (8) User I/Os
- Single programmable current output (LED)
- Operating Voltage:
- Single supply 2.7V to 6.5V operation (VPC)
- 5V supply (VBUS 4.4V to 5.5V) with or without battery back up operation (VBAT 4.0V to 6.5V)
- Automated detection of voltage presence - Priority on VBUS over VBAT

DC-DC Converter:

- Requires a single 10μH Inductor
- 3.3V / 20mA supply available for external circuits

Operating Temperature:

- -40°C to 85°C

Package:

- 68-pin QFN, 44 pin QFN

Turnkey Firmware:

- Compliant with PC/SC, ISO7816 and EMV4.1 specifications
- Features a Power Down mode accessible from the host
- Supports Plug & Play over serial interface
- Windows® XP driver available (*)
- Windows CE / Mobile driver available (*)
- Linux and other OS: Upon request
- Or for custom developments:
  - A complete set of ISO-7816, EMV4.1 and low-level libraries are available for T=0 / T=1
  - Two-level Application Programming Interface (ANSI C-language libraries)

(*) Contact Teridian Semiconductor for conditions and availability.

1 Hardware Description

1.1 Pin Description

Table 1: 73S1210 Pinout Description

Pin Name	Pin (68 QFN)	Pin (44 QFN)	Type	Equivalent Circuit*	Description
X12IN	10	9	I	Figure 26	MPU clock crystal oscillator input pin. A 1MΩ resistor is required between pins X12IN and X12OUT.
X12OUT	11	10	O	Figure 26	MPU clock crystal oscillator output pin.
ROW(5:0) 0 1 2 3 4 5	 21 22 24 33 36 37		I	Figure 34	Keypad row input sense.
COL(4:0) 0 1 2 3 4	 12 13 14 16 19		O	Figure 35	Keypad column output scan pins.
USR(7:0) 0 1 2 3 4 5 6 7	 35 34 32 31 30 29 23 20	 22 21 20 19 18 17 14 13	IO	Figure 30	General-purpose user pins, individually configurable as inputs or outputs or as external input interrupt ports.
SCL	5	6	O	Figure 29	I^2C (master mode) compatible Clock signal. Note: the pin is configured as an open drain output. When the I2C interface is being used, an external pull up resistor is required. A value of 3K is recommended.
SDA	6	7	IO	Figure 28	I^2C (master mode) compatible data I/O. Note: this pin is bi-directional. When the pin is configured as output, it is an open drain output. When the I2C interface is being used, an external pull up resistor is required. A value of 3K is recommended.
RXD	17	11	I	Figure 32	Serial UART Receive data pin.
TXD	18	12	O	Figure 29	Serial UART Transmit data pin.
INT3	48	30	I	Figure 32	General purpose interrupt input.
INT2	49	31	I	Figure 32	General purpose interrupt input.
SIO	47	29	IO	Figure 28	IO data signal for use with external Smart Card interface circuit such as 73S8010.
SCLK	45	28	O	Figure 29	Clock signal for use with external Smart Card interface circuit.

Pin Name	Pin (68 QFN)	Pin (44 QFN)	Type	Equivalent Circuit*	Description
PRES	53	34	I	Figure 41	Smart Card presence. Active high. Note: the pin has a very weak pull down resistor. In noisy environments, an external pull down may be desired to insure against a false card event.
CLK	55	36	O	Figure 39	Smart Card clock signal.
RST	57	38	O	Figure 39	Smart Card reset signal.
IO	61	42	IO	Figure 40	Smart Card Data IO signal.
AUX1	60	41	IO	Figure 40	Auxiliary Smart Card IO signal (C4).
AUX2	59	40	IO	Figure 40	Auxiliary Smart Card IO signal (C8).
VCC	58	39	PSO		Smart Card VCC supply voltage output. A 0.47µF capacitor is required and should be located at the smart card connector. The capacitor should be a ceramic type with low ESR.
GND	56	37	GND		Smart Card Ground.
VPC	65	44	PSI		Power supply source for main voltage converter circuit. A 10µF and a 0.1µF capacitor are required at the VPC input. The 10µF capacitor should be a ceramic type with low ESR.
VBUS	62		PSI		Alternate power source input from external power supply.
VBAT	64		PSI		Alternate power source input, typically from two series cells, V > 4V.
VP	54	35	PSO		Intermediate output of main converter circuit. Requires an external 4.7µF low ESR filter capacitor to GND.
LIN	66	1	PSI		Connection to 10µH inductor for internal step up converter. Note: inductor must be rated for 400 mA maximum peak current.
ON_OFF	63	43	I	Figure 43	Power control pin. Connected to normally open SPST switch to ground. Closing switch for duration greater than debounce period will turn 73S1210F on. If 73S1210F is on, closing switch will flag the 73S1210F to go to the off state. Firmware will control when the power is shut down.
OFF_REQ	52	33	O	Figure 33	Digital output. If ON_OFF switch is closed (to ground) for debounce duration and circuit is “on,” OFF_REQ will go high (Request to turn OFF). This output should be connected to an interrupt pin to signal the CPU core that a request to shut down power has been initiated. The firmware can then perform all of its shut down housekeeping duties before shutting down V_{DD}.
TBUS(3:0) 0 1 2 3	 50 46 44 41		IO		Trace bus signals for ICE.

Pin Name	Pin (68 Qfn)	Pin (44 QFN)	Type	Equivalent Circuit*	Description
RXTX	43	27	IO		ICE control.
ERST	38	23	IO		ICE control.
ISBR	3		IO		ICE control.
TCLK	39	24	I		ICE control.
ANA_IN	15		AI	Figure 38	Analog input pin. This signal goes to a programmable comparator and is used to sense the value of an external voltage.
SEC	2		I	Figure 37	Input pin for use in programming security fuse. It should be connected to ground when not in use.
TEST	51	32	DI	Figure 37	Test pin, should be connected to ground
LED0	4	5	IO	Figure 36	Special output driver, programmable pull-down current to drive LED. May also be used as an input.
VDD	68 28 40	3 16 25	PSO		V_{DD} supply output pin. A 0.1µF capacitor is recommended at each VDD pin.
N/C	7 8 26 27				No connect.
GND	9 25 42 67	2 8 15 26	GND		General ground supply pins for all IO and logic circuits.
RESET	1	4	I	Figure 32	Reset input, positive assertion. Resets logic and registers to default condition. Note: to insure proper reset operation after V_{DD} is turned on by application of V_{BUS} power or activation of the ON/OFF switch, external reset circuitry must generate a proper reset signal to the 73S1210F. This can be accomplished via a simple RC network.

* See the figures in the Equivalent Circuits section.

1.2 Hardware Overview

The 73S1210F single smart card controller integrates all primary functional blocks required to implement a smart card reader. Included on chip are an 8051-compatible microprocessor (MPU) which executes up to one instruction per clock cycle (80515), a fully integrated IS0 7816 compliant smart card interface, expansion smart card interface, serial interface, I2C interface, 6 x 5 keypad interface, RAM, FLASH memory, and a variety of I/O pins.

The power management circuitry provides a 3.3V voltage output (VDD, pin #68) that must be connected to the power supply inputs of the digital core of the circuit, pins # 28 and 40 (these are not internally connected). Should external circuitry require a 3.3V digital power supply, the VDD output is capable of supplying additional current.

Figure 1 shows a functional block diagram of the 73S1210F.

1.3 80515 MPU Core

1.3.1 80515 Overview

The 73S1210F includes an 80515 MPU (8-bit, 8051-compatible) that performs most instructions in one clock cycle. The 80515 architecture eliminates redundant bus states and implements parallel execution of fetch and execution phases. Normally a machine cycle is aligned with a memory fetch, therefore, most of the 1-byte instructions are performed in a single cycle. This leads to an 8x performance (average) improvement (in terms of MIPS) over the Intel 8051 device running at the same clock frequency.

Actual processor clocking speed can be adjusted to the total processing demand of the application (cryptographic calculations, key management, memory management, and I/O management) using the XRAM special function register MPUCKCtl.

Typical smart card, serial, keyboard and I2C management functions are available for the MPU as part of the Teridian standard library. A standard ANSI “C” 80515-application programming interface library is available to help reduce design cycle. Refer to the *73S12xxF Software User’s Guide*.

1.3.2 Memory Organization

The 80515 MPU core incorporates the Harvard architecture with separate code and data spaces. Memory organization in the 80515 is similar to that of the industry standard 8051. There are three memory areas: Program memory (Flash), external data memory (XRAM), and internal data memory (IRAM). Data bus address space is allocated to on-chip memory as shown Table 2

Table 2: MPU Data Memory Map

Address (hex)	Memory Technology	Memory Type	Typical Usage	Memory Size (bytes)
0000-7FFF	Flash Memory	Non-volatile	Program and non-volatile data	32KB
0000-07FF	Static RAM	Volatile	MPU data XRAM	2KB
FC00-FFFF	External SFR	Volatile	Peripheral control	1KB

Note: The IRAM is part of the core and is addressed differently.

Program Memory: The 80515 can address up to 32KB of program memory space from 0x0000 to 0xFFFF. Program memory is read when the MPU fetches instructions or performs a MOVC operation. After reset, the MPU starts program execution from location 0x0000. The lower part of the program memory includes reset and interrupt vectors. The interrupt vectors are spaced at 8-byte intervals, starting from 0x0003. Reset is located at 0x0000.

Flash Memory: The program memory consists of flash memory. The flash memory is intended to primarily contain MPU program code. Flash erasure is initiated by writing a specific data pattern to

specific SFR registers in the proper sequence. These special pattern/sequence requirements prevent inadvertent erasure of the flash memory.

The mass erase sequence is:

1. Write 1 to the FLSH_MEEN bit in the FLSHCTL register (SFR address 0xB2[1]).
2. Write pattern 0xAA to ERASE (SFR address 0x94).

Note: The mass erase cycle can only be initiated when the ICE port is enabled.

The page erase sequence is:

1. Write the page address to PGADDR (SFR address 0xB7[7:1]).
2. Write pattern 0x55 to ERASE (SFR address 0x94).

The PGADDR register denotes the page address for page erase. The page size is 512 (200h) bytes and there are 128 pages within the flash memory. The PGADDR denotes the upper seven bits of the flash memory address such that bit 7:1 of the PGADDR corresponds to bit 15:9 of the flash memory address. Bit 0 of the PGADDR is not used and is ignored. The MPU may write to the flash memory. This is one of the non-volatile storage options available to the user. The FLSHCTL SFR bit FLSH_PWE (flash program write enable) differentiates 80515 data store instructions (MOVX@DPTR,A) between Flash and XRAM writes. Before setting FLSH_PWE, all interrupts need to be disabled by setting EAL = 1. Table 3 shows the location and description of the 73S1210 flash-specific SFRs.

Any flash modifications must set the CPUCLK to operate at 3.6923 MHz (MPUCLKCtl = 0x0C) before any flash memory operations are executed to insure the proper timing when modifying the flash memory.

Table 3: Flash Special Function Registers

Register	SFR Address	R/W	Description
ERASE	0x94	W	This register is used to initiate either the Flash Mass Erase cycle or the Flash Page Erase cycle. Specific patterns are expected for ERASE in order to initiate the appropriate Erase cycle (default = 0x00). 0x55 – Initiate Flash Page Erase cycle. Must be proceeded by a write to PGADDR @ SFR 0xB7. 0xAA – Initiate Flash Mass Erase cycle. Must be proceeded by a write to FLSH_MEEN @ SFR 0xB2 and the debug port must be enabled. Any other pattern written to ERASE will have no effect.
PGADDR	0xB7	R/W	Flash Page Erase Address register containing the flash memory page address (page 0 through 127) that will be erased during the Page Erase cycle (default = 0x00). Note: the page address is shifted left by one bit (see detailed description above). Must be re-written for each new Page Erase cycle.
FLSHCTL	0xB2	R/W	Bit 0 (FLSH_PWE): Program Write Enable: 0 – MOVX commands refer to XRAM Space, normal operation (default). 1 – MOVX @DPTR,A moves A to Program Space (Flash) @ DPTR. This bit is automatically reset after each byte written to flash. Writes to this bit are inhibited when interrupts are enabled.
		W	Bit 1 (FLSH_MEEN): Mass Erase Enable: 0 – Mass Erase disabled (default). 1 – Mass Erase enabled. Must be re-written for each new Mass Erase cycle.
		R/W	Bit 6 (SECURE): Enables security provisions that prevent external reading of flash memory and CE program RAM. This bit is reset on chip reset and may only be set. Attempts to write zero are ignored.

Internal Data Memory: The Internal data memory provides 256 bytes (0x00 to 0xFF) of data memory. The internal data memory address is always one byte wide and can be accessed by either direct or indirect addressing. The Special Function Registers occupy the upper 128 bytes**. This SFR area is available only by direct addressing. Indirect addressing accesses the upper 128 bytes of Internal RAM.**

The lower 128 bytes contain working registers and bit-addressable memory. The lower 32 bytes form four banks of eight registers (R0-R7). Two bits on the program memory status word (PSW) select which bank is in use. The next 16 bytes form a block of bit-addressable memory space at bit addresses 0x00-0x7F. All of the bytes in the lower 128 bytes are accessible through direct or indirect addressing. Table 4 shows the internal data memory map.

Table 4: Internal Data Memory Map

Address	Direct Addressing	Indirect Addressing
0xFF	Special Function Registers (SFRs)	RAM
0x80		
0x7F	Byte-addressable area	
0x30		
0x2F	Byte or bit-addressable area	
0x20		
0x1F	Register banks R0…R7 (x4)	
0x00		

External Data Memory: While the 80515 can address up to 64KB of external data memory in the space from 0x0000 to 0xFFFF, only the memory ranges shown in Figure 2 contain physical memory. The 80515 writes into external data memory when the MPU executes a MOVX @Ri,A or MOVX @DPTR,A instruction. The MPU reads external data memory by executing a MOVX A,@Ri or MOVX A,@DPTR instruction.

There are two types of instructions, differing in whether they provide an eight-bit or sixteen-bit indirect address to the external data RAM.

In the first type (MOVX A,@Ri), the contents of R0 or R1, in the current register bank, provide the eight lower-ordered bits of address. This method allows the user access to the first 256 bytes of the 2KB of external data RAM. In the second type of MOVX instruction (MOVX A,@DPTR), the data pointer generates a sixteen-bit address.

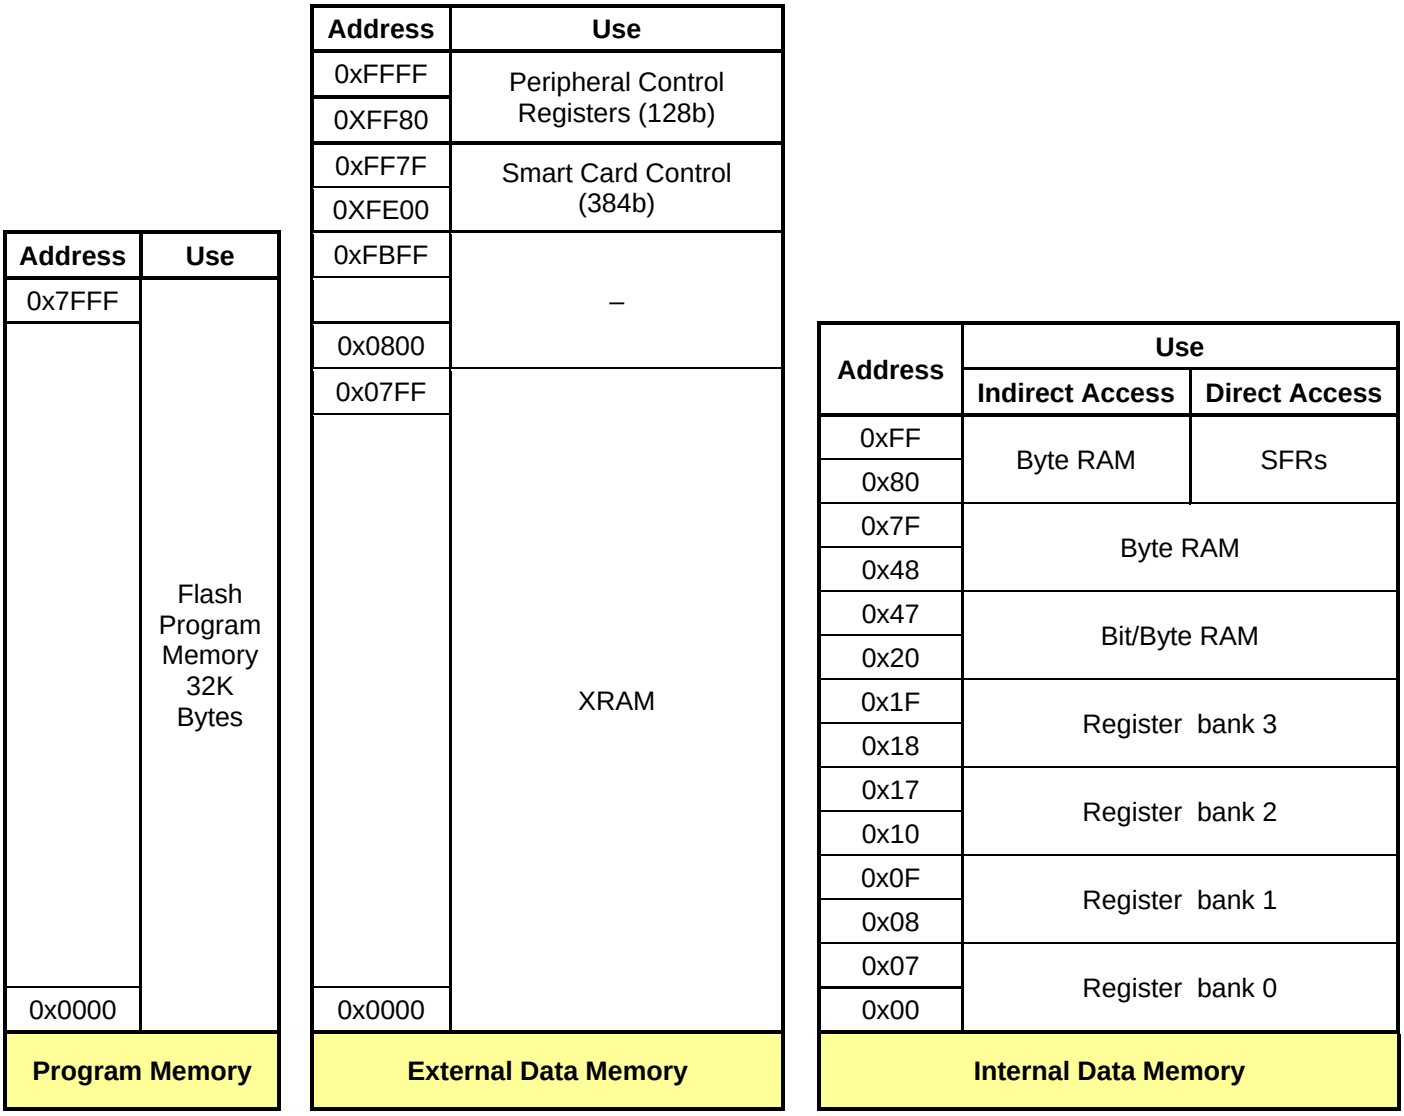

Figure 2: Memory Map

Dual Data Pointer: The Dual Data Pointer accelerates the block moves of data. The standard DPTR is a 16-bit register that is used to address external memory. In the 80515 core, the standard data pointer is called DPTR, the second data pointer is called DPTR1. The data pointer select bit chooses the active pointer. The data pointer select bit is located at the LSB of the DPS IRAM special function register (DPS.0). DPTR is selected when DPS.0 = 0 and DPTR1 is selected when DPS.0 = 1.

The user switches between pointers by toggling the LSB of the DPS register. All DPTR-related instructions use the currently selected DPTR for any activity.

The second data pointer may not be supported by certain compilers.

1.4 Program Security

Two levels of program and data security are available. Each level requires a specific fuse to be blown in order to enable or set the specific security mode. Mode 0 security is enabled by setting the SECURE bit (bit 6 of SFR register FLSHCTL 0xB2). Mode 0 limits the ICE interface to only allow bulk erase of the flash program memory. All other ICE operations are blocked. This guarantees the security of the user's MPU program code. Security (Mode 0) is enabled by MPU code that sets the SECURE bit. The MPU code must execute the setting of the SECURE bit immediately after a reset to properly enable Mode 0. This should be the first instruction after the reset vector jump has been executed. If the "startup.a51" assembly file is used in an application, then it must be modified to set the SECURE bit after the reset vector jump. If not using "startup.a51", then this should be the first instruction in main(). Once security Mode 0 is enabled, the only way to disable it is to perform a global erase of the flash followed by a full circuit reset. Once the flash has been erased and the reset has been executed, security Mode 0 is disabled and the ICE has full control of the core. The flash can be reprogrammed after the bulk erase operation is completed. Global erase of the flash will also clear the data XRAM memory.

The security enable bit (SECURE) is reset whenever the MPU is reset. Hardware associated with the bit only allows it to be set. As a result, the code may set the SECURE bit to enable the security Mode 0 feature but may not reset it. Once the SECURE bit is set, the code is protected and no external read of program code in flash or data (in XRAM) is possible. In order to invoke the security Mode 0, the SECSET0 (bit 1 of the XRAM SFR register SECReg 0xFFD7) fuse must be blown beforehand or the security mode 0 will not be enabled. The SECSET0 and SECSET1 fuses once blown, cannot be overridden.

Specifically, when SECURE is set:

- The ICE is limited to bulk flash erase only.
- Page zero of flash memory, the preferred location for the user's preboot code, may not be page-erased by either MPU or ICE. Page zero may only be erased with global flash erase. Note that global flash erase erases XRAM whether the SECURE bit is set or not.
- Writes to page zero, whether by MPU or ICE, are inhibited.

Security mode 1 is in effect when the SECSET1 fuse has been programmed (blown open). In security mode 1, the ICE is completely and permanently disabled. The Flash program memory and the MPU are not available for alteration, observation, nor control. As soon as the fuse has been blown, the ICE is disabled. The testing of the SECSET1 fuse will occur during the reset and before the start of pre-boot and boot cycles. This mode is not reversible, nor recoverable. In order to blow the SECSET1 fuse, the SEC pin must be held high for the fuse burning sequence to be executed properly. The firmware can check to see if this pin is held high by reading the SECPIN bit (bit 5 of XRAM SFR register SECReg 0xFFD7). If this bit is set and the firmware desires, it can blow the SECSET1 fuse. The burning of the SECSET0 does not require the SEC pin to be held high.

In order to blow the fuse for SECSET1 and SECSET0, a particular set of register writes in a specific order need to be followed. There are two additional registers that need to have a specific value written to them in order for the desired fuse to be blown. These registers are FUSECtl (0xFFD2) and TRIMPCtl (0xFFD1). The sequence for blowing the fuse is as follows:

1. Write 0x54H to FUSECtl.
2. Write 0x81H for security mode 0. Note: only program one security mode at a time.
   Write 0x82H for security mode 1. Note: SEC pin must be high for security mode 1.
3. Write 0xA6 to TRIMPCtl.
4. Delay about 500 µs.
5. Write 0x00 to TRIMPCtl and FUSECtl.

Table 5: Program Security Registers

Register	SFR Address	R/W	Description
FLSHCTL	0xB2	R/W	Bit 0 (FLSH_PWE): Program Write Enable: 0 – MOVX commands refer to XRAM Space, normal operation (default). 1 – MOVX @DPTR,A moves A to Program Space (Flash) @ DPTR. This bit is automatically reset after each byte written to flash. Writes to this bit are inhibited when interrupts are enabled.
		W	Bit 1 (FLSH_MEEN): Mass Erase Enable: 0 – Mass Erase disabled (default). 1 – Mass Erase enabled. Must be re-written for each new Mass Erase cycle.
		R/W	Bit 6 (SECURE): Enables security provisions that prevent external reading of flash memory and CE program RAM. This bit is reset on chip reset and may only be set. Attempts to write zero are ignored.
TRIMPCtl	0xFFD1	W	0x54 value will set up for security fuse control. All other values are reserved and should not be used.
FUSECtl	0xFFD2	W	0xA6 value will cause the selected fuse to be blown. All other values will stop the burning process.
SECReg	0xFFD7	W	Bit 7 (PARAMSEC): 0 – Normal operation. 1 – Enable permanent programming of the security fuses.
		R	Bit 5 (SECPIN): Indicates the state of the SEC pin. The SEC pin is held low by a pull-down resistor. The user can force this pin high during boot sequence time to indicate to firmware that sec mode 1 is desired.
		R/W	Bit 1 (SECSET1): See the Program Security section.
		R/W	Bit 0 (SECSET0): See the Program Security section.

1.5 Special Function Registers (SFRs)

The 73S1210F utilizes numerous SFRs to communicate with the 73S1210Fs many peripherals. This results in the need for more SFR locations outside the direct address IRAM space (0x80 to 0xFF). While some peripherals are mapped to unused IRAM SFR locations, additional SFRs for the smart card and other peripheral functions are mapped to the top of the XRAM data space (0xFC00 to 0xFFFF).

1.5.1 Internal Data Special Function Registers (SFRs)

A map of the Special Function Registers is shown in Table 6.

Table 6: IRAM Special Function Registers Locations

Only a few addresses are used, the others are not implemented. SFRs specific to the 73S1210F are shown in **bold** print (gray background). Any read access to unimplemented addresses will return undefined data, while most write access will have no effect. However, a few locations are reserved and not user configurable in the 73S1210F. **Writes to the unused SFR locations can affect the operation of the core and therefore must not be written to. This applies to all the SFR areas in both the IRAM and XRAM spaces. In addition, all unused bit locations within valid SFR registers must be left in their default (power on default) states.**

1.5.2 IRAM Special Function Registers (Generic 80515 SFRs)

Table 7 shows the location of the SFRs and the value they assume at reset or power-up.

Table 7: IRAM Special Function Registers Reset Values

Name	Location	Reset Value	Description
SP	0x81	0x07	Stack Pointer
DPL	0x82	0x00	Data Pointer Low 0

TRIMPCtl	0x FFD1	0x00	TRIM Pulse Control
FUSECtl	0x FFD2	0x00	FUSE Control
VDDFCtl	0x FFD4	0x00	VDDFault Control
SECReg	0x FFD7	0x00	Security Register
MISCtl0	0x FFF1	0x00	Miscellaneous Control Register 0
MISCtl1	0x FFF2	0x10	Miscellaneous Control Register 1
LEDCtl	0x FFF3	0xFF	LED Control Register

Accumulator (ACC, A): ACC is the accumulator register. Most instructions use the accumulator to hold the operand. The mnemonics for accumulator-specific instructions refer to accumulator as “A”, not ACC.

B Register: The B register is used during multiply and divide instructions. It can also be used as a scratch-pad register to hold temporary data.

Program Status Word (PSW):

Table 9: PSW Register

MSB							LSB
CV	AC	F0	RS1	RS	OV	–	P

Bit	Symbol	Function
PSW.7	CV	Carry flag.
PSW.6	AC	Auxiliary Carry flag for BCD operations.
PSW.5	F0	General purpose Flag 0 available for user.
PSW.4	RS1	Register bank select control bits. The contents of RS1 and RS0 select the working register bank:
PSW.3	RS0	
PSW.2	OV	Overflow flag.
PSW.1	F1	General purpose Flag 1 available for user.
PSW.0	P	Parity flag, affected by hardware to indicate odd / even number of “one” bits in the Accumulator, i.e. even parity.

RS1/RS0	Bank Selected	Location
00	Bank 0	(0x00 – 0x07)
01	Bank 1	(0x08 – 0x0F)
10	Bank 2	(0x10 – 0x17)
11	Bank 3	(0x18 – 0x1F)

Stack Pointer: The stack pointer (SP) is a 1-byte register initialized to 0x07 after reset. This register is incremented before PUSH and CALL instructions, causing the stack to begin at location 0x08.

Data Pointer: The data pointer (DPTR) is 2 bytes wide. The lower part is DPL, and the highest is DPH. It can be loaded as a 2-byte register (MOV DPTR,#data16) or as two registers (e.g. MOV DPL,#data8). It is generally used to access external code or data space (e.g. MOVC A,@A+DPTR or MOVX A,@DPTR respectively).

Program Counter: The program counter (PC) is 2 bytes wide initialized to 0x0000 after reset. This register is incremented during the fetching operation code or when operating on data from program memory. Note: The program counter is not mapped to the SFR area.

Port Registers: The I/O ports are controlled by Special Function Register USR70. The contents of the SFR can be observed on corresponding pins on the chip. Writing a 1 to any of the ports (see Table 10) causes the corresponding pin to be at high level (3.3V), and writing a 0 causes the corresponding pin to be held at low level (GND). The data direction register UDIR70 define individual pins as input or output pins (see the User (USR) Ports section for details).

Table 10: Port Registers

Register	SFR Address	R/W	Description
USR70	0x90	R/W	Register for User port bit 7:0 read and write operations (pins USR0… USR7).
UDIR70	0x91	R/W	Data direction register for User port bits 0:7. Setting a bit to 0 means that the corresponding pin is an output.

All ports on the chip are bi-directional. Each consists of a Latch (SFR 'USR70'), an output driver, and an input buffer, therefore the MPU can output or read data through any of these ports if they are not used for alternate purposes.

1.6 Instruction Set

All instructions of the generic 8051 microcontroller are supported. A complete list of the instruction set and of the associated op-codes is contained in the *73S12xxF Software User's Guide*.

1.7 Peripheral Descriptions

1.7.1 Oscillator and Clock Generation

The 73S1210F has one oscillator circuit for the main CPU clock. The main oscillator circuit is designed to operate with various crystal or external clock frequencies. An internal divider working in conjunction with a PLL and VCO provides a 96MHz internal clock within the 73S1210F. 96 MHz is the recommended frequency for proper operation of specific peripheral blocks such as the specific timers, ISO 7816 UART and interfaces, Step-up converter, and keypad. The clock generation and control circuits are shown in Figure 3.

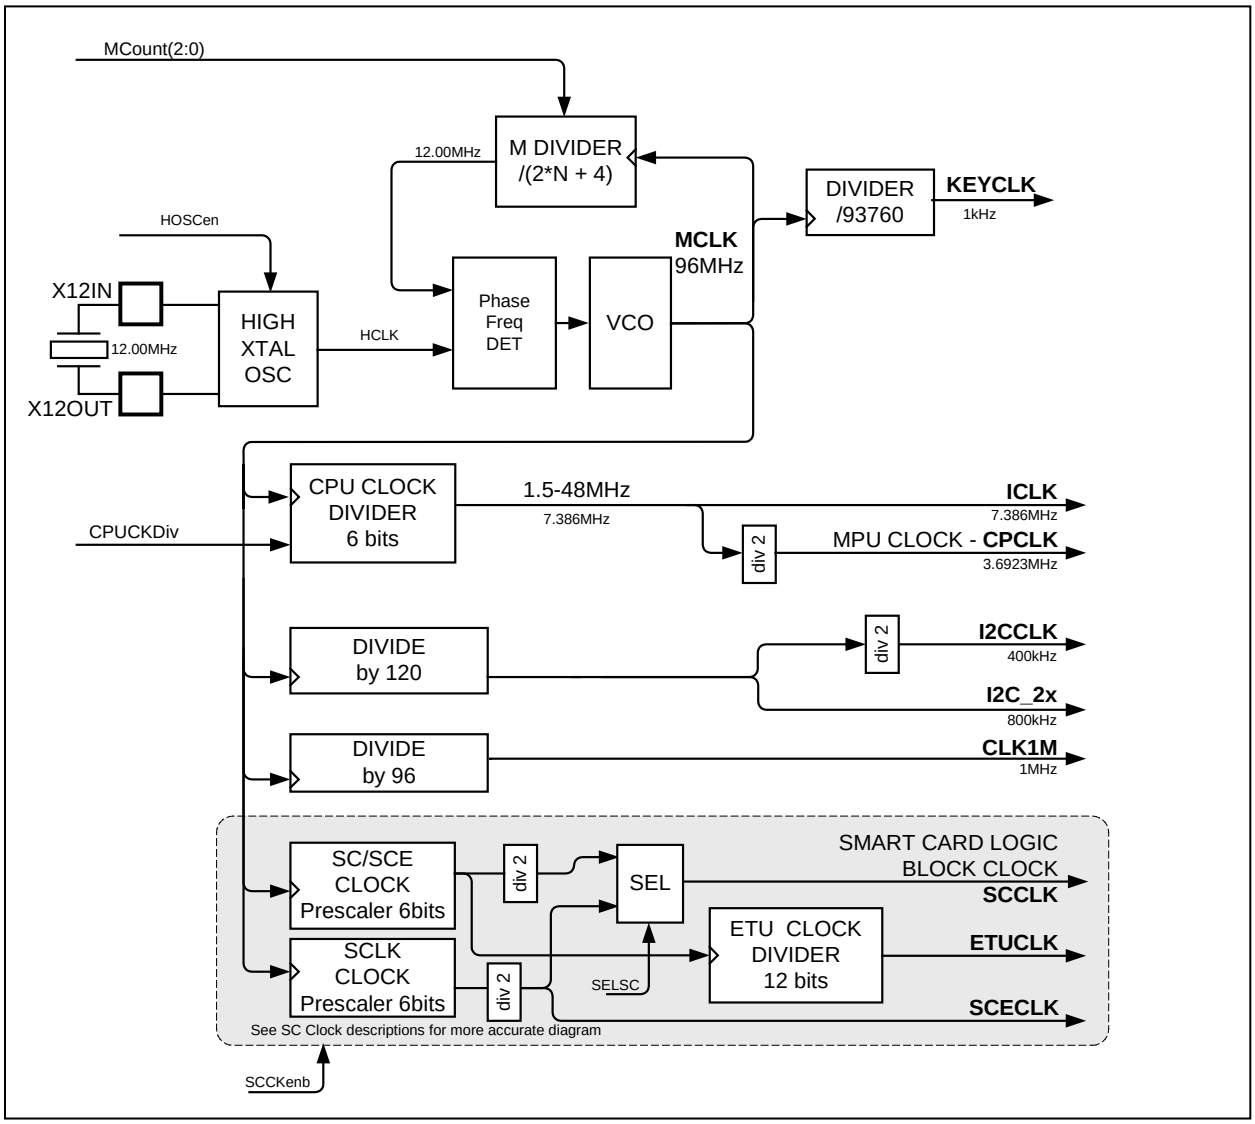

Figure 3: Clock Generation and Control Circuits

The master clock control register enables different sections of the clock circuitry and specifies the value of the VCO Mcount divider. The MCLK must be configured to operate at 96MHz to ensure proper operation of some of the peripheral blocks according to the following formula:

$$MCLK = (Mcount * 2 + 4) * F_{XTAL} = 96MHz$$

Mcount is configured in the MCLKCtl register must be bound between a value of 1 to 10. The possible crystal or external clock frequencies for getting MCLK = 96MHz are shown in Table 11.

Table 11: Frequencies and Mcount Values for MCLK = 96MHz

F_{XTAL} (MHz)	Mcount (N)
12.00	2
9.60	3
8.00	4
6.86	5
6.00	6

Master Clock Control Register (MCLKCtl): 0x8F ← 0x0A

The MPU clock that drives the CPU core defaults to 3.6923MHz after reset. The MPU clock is scalable by configuring the MPU Clock Control register.

Table 12: The MCLKCtl Register

MSB LSB

HSOEN	KBEN	SCEN	–	–	MCT.2	MCT.1	MCT.0

Bit	Symbol	Function
MCLKCtl.7	HSOEN	High-speed oscillator disable. When set = 1, disables the high-speed crystal oscillator and VCO/PLL system. Do not set this bit = 1.
MCLKCtl.6	KBEN	1 = Disable the keypad logic clock.
MCLKCtl.5	SCEN	1 = Disable the smart card logic clock.
MCLKCtl.4	–	
MCLKCtl.3	–	
MCLKCtl.2	MCT.2	This value determines the ratio of the VCO frequency (MCLK) to the high-speed crystal oscillator frequency such that: MCLK = (MCount*2 + 4)* F_{XTAL}. The default value is MCount = 2h such that MCLK = (2*2 + 4)*12.00MHz = 96MHz.
MCLKCtl.1	MCT.1	
MCLKCtl.0	MCT.0	

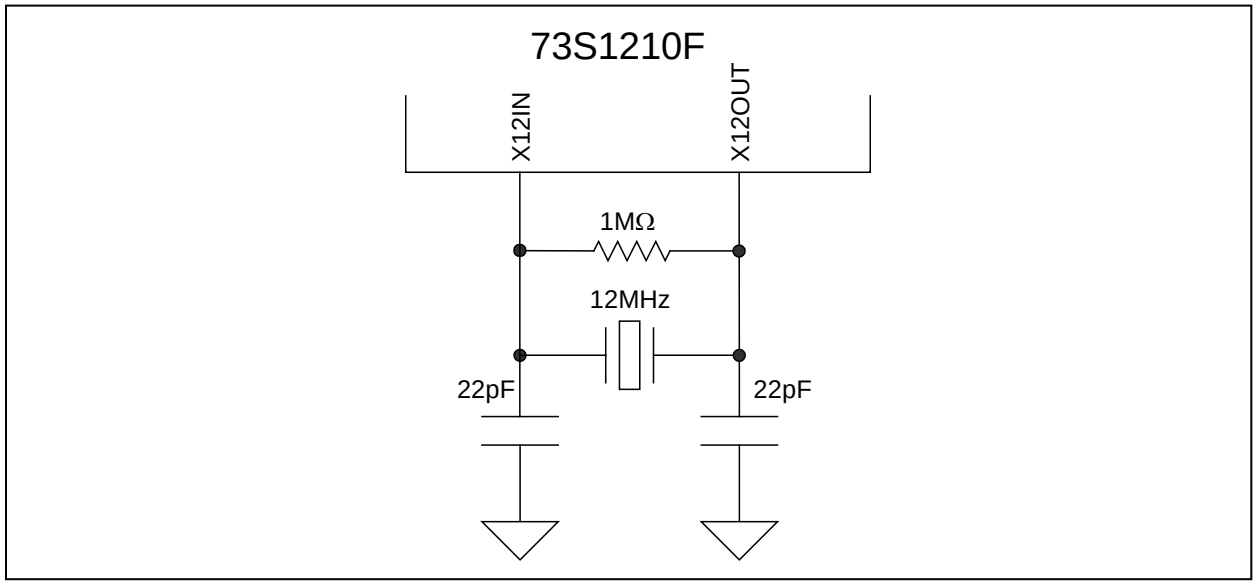
MPU Clock Control Register (MPUCKCtl): 0xFFA1 ← 0x0C

Table 13: The TCON Register

MSB							LSB
–	–	MDIV.5	MDIV.4	MDIV.3	MDIV.2	MDIV.1	MDIV.0

Bit	Symbol	Function
MPUCKCtl.7	–	
MPUCKCtl.6	–	
MPUCKCtl.5	MDIV.5	This value determines the ratio of the MPU master clock frequency to the VCO frequency (MCLK) such that MPUClk = MCLK/(2 * (MPUCKDiv(5:0) + 1)). Do not use values of 0 or 1 for MPUCKDiv(n). Default is 0Ch to set CPCLK = 3.6923MHz.
MPUCKCtl.4	MDIV.4	
MPUCKCtl.3	MDIV.3	
MPUCKCtl.2	MDIV.2	
MPUCKCtl.1	MDIV.1	
MPUCKCtl.0	MDIV.0	

The oscillator circuits are designed to connect directly to standard parallel resonant crystal in a Pierce oscillator configuration. Each side of the crystal should include a 22pF capacitor to ground for both oscillator circuits and a 1MΩ resistor is required across the 12MHz crystal.



Note: The crystal should be placed as close as possible to the IC, and vias should be avoided.

Figure 4: Oscillator Circuit

1.7.2 Power Supply Management

The detailed power supply management logic block diagram is shown in Figure 5.

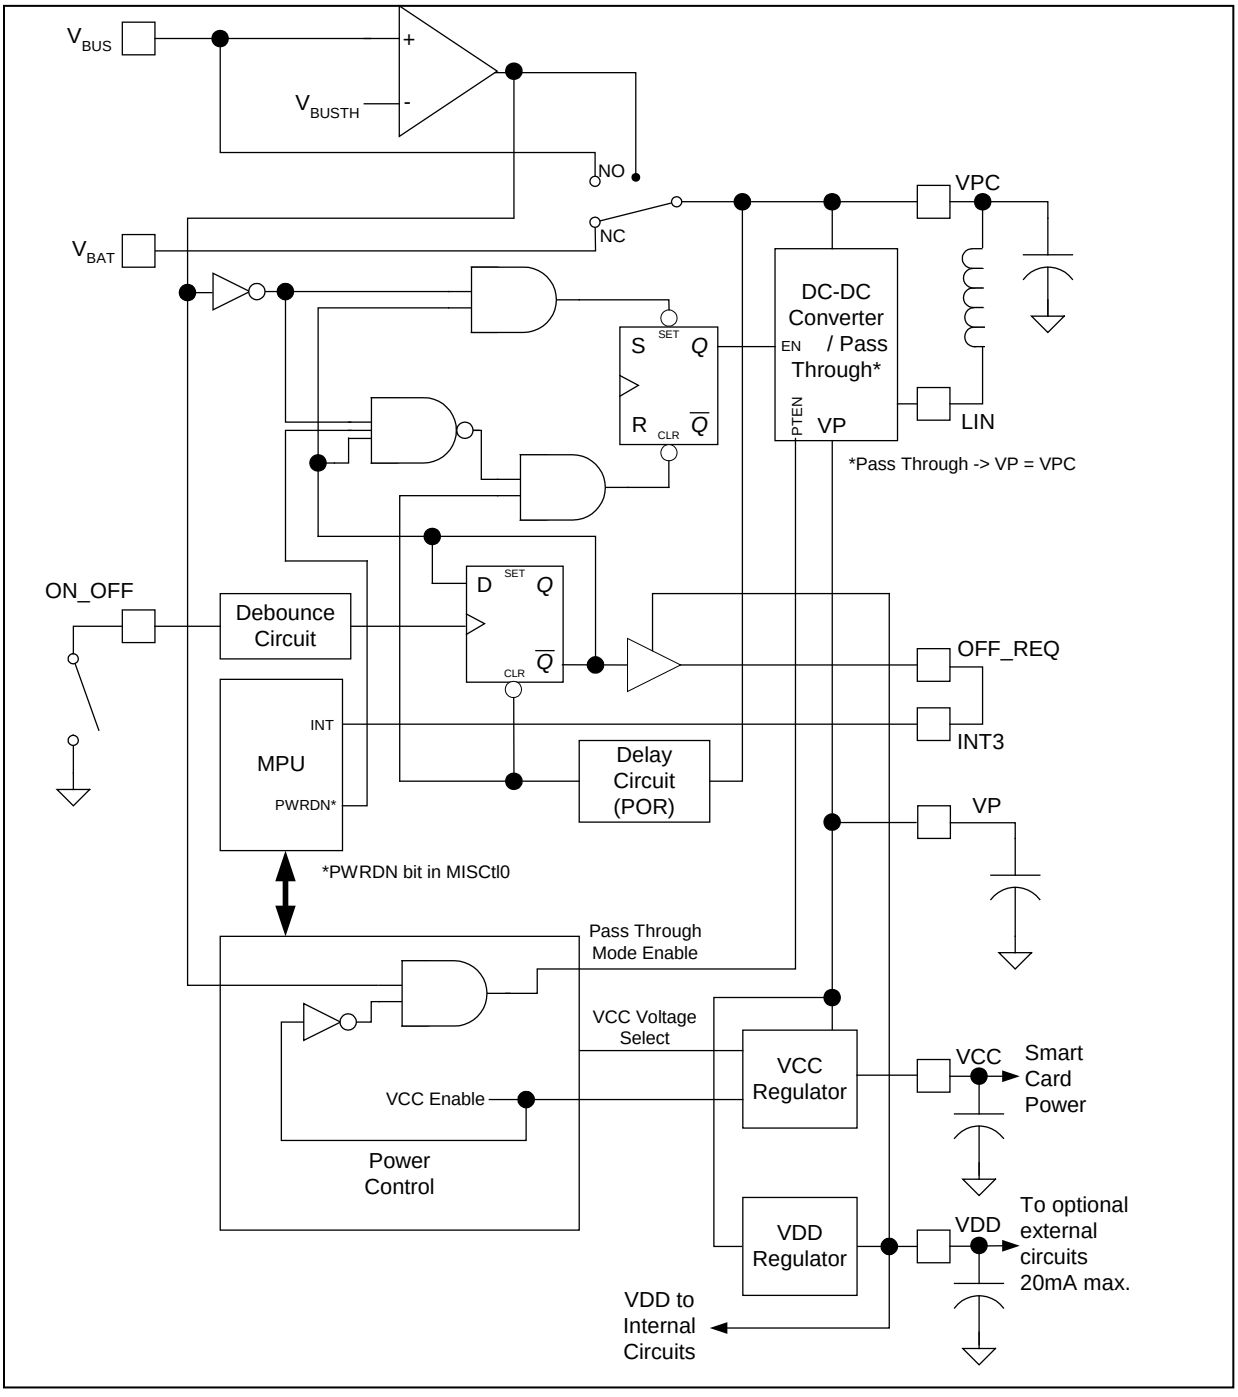


Figure 5: Detailed Power Management Logic Block Diagram

The 73S1210F contains a power supply and converter circuit that takes power from any one of three sources; V_{PC}, V_{BUS}, or V_{BAT}.

V_{PC} is specified to range from 2.7 to 6.5 volts. It can typically be supplied by a single cell battery with a voltage range of 2.7 to approximately 3.1 volts or by a standard supply of 3.3 or 5 volts.

V_{BUS} is typically supplied by an external power supply and ranges in value from 4.4 to 5.5 volts (6.5V maximum).

V_{BAT} is expected to be supplied from a battery of three to four series connected cells with a voltage value of 4.0 to 6.5 volts.

V_{BAT} and V_{BUS} are internally switched to V_{PC} by two separate FET switches configured as a SPDT switch (break-before-make). They will not be enabled at the same time. V_{BUS} is automatically selected in lieu of V_{BAT} when V_{BUS} is present (i.e. V_{BUS} always has the priority).

If V_{PC} is provided and either V_{BAT} or V_{BUS} is also used, the source of V_{PC} must be diode isolated from the V_{PC} pin to prevent current flow from V_{BAT} or V_{BUS} into the V_{PC} source.

The power that is supplied to the V_{PC} pin (externally or internally, i.e. through V_{BAT} or V_{BUS} – see above) is up-converted to the intermediate voltage V_P utilizing an inductive, step-up converter. A series power inductor (nominal value = 10 μH) must be connected from V_{PC} to the pin LIN, and a 10μF low ESR filter capacitor must be connected to V_{PC}.

V_P requires a 4.7μF filter capacitor and will have a nominal value of 5.5 volts during normal operation. V_P is used internally by the smart card electrical interface circuit and is regulated to the desired smart card supply V_{CC} voltage (can be programmed for values of 5V, 3V, or 1.8V).

V_P is also used internally to generate a 3.3V nominal, regulated power supply V_{DD}. V_{DD} is output on pin 68 and must be directly tied to all other V_{DD} pins on the 73S1210F (pins 28 and 40). V_{DD} powers all the digital logic, input/output buffering, and analog functions. It can also be used for external circuitry: up to 20mA current can be supplied to external devices simultaneously to the 73S1210F's digital core maximum consumption.

1.7.3 Power ON/OFF

The 73S1210F features an ON_OFF input pin for a momentary contact, main-system ON/OFF switch. The purpose of this switch is to place the circuit in a very low-power mode – the "OFF" mode – where all circuits are no longer powered, therefore allowing the lowest possible current consumption.

When in "OFF" mode, an action on the ON/OFF switch will turn-on the power supply of the digital core (V_{DD}) and apply a power-on-reset condition. Alternatively, entering the "OFF" mode from the "ON" mode requires firmware action.

When in "ON" mode, an action on the ON/OFF switch will send a request to the controller that will have to be acknowledged (firmware action required) in order to enter the "OFF" state.

When placed into the "OFF" state, the 73S1210F will consume minimum current from V_{PC} and V_{BAT}; V_P and V_{DD} will be unavailable (V_{DD} out = 0V and V_P = 0V).

When in "ON" mode, the 73S1210F will operate normally, with all the features described in this document available. V_P and V_{DD} will be available (V_{DD} out = 3.3V and V_P = 5.5V nominal).

Whenever V_{BUS} power is supplied, the circuit will be automatically in the "ON" state. The functions of the ON/OFF switch and circuitry are overridden and the 73S1210F is in the "ON" state with V_P and V_{DD} available.

Without V_{BUS} applied, the circuit is by default in the "OFF" state, and will respond only to the ON_OFF pin. The ON_OFF pin should be connected to an SPST switch to ground. If the circuit is OFF and the switch is closed for a debounce period of 50-100ms, the circuit will go into the "ON" state wherein all functions are operating in normal fashion. If the circuit is in the "ON" state and the ON/OFF pin is connected to ground for a period greater than the debounce period, OFF_REQ will be asserted high and held regardless of the state of ON/OFF. The OFF_REQ signal should be connected to one of the interrupt pins to signal the CPU core that a request to shutdown has been initiated. The firmware will acknowledge this request by setting the SCPWRDN bit in the Smart Card V_{CC} Control/Status Register (VccCtl) high after it has completed all shutdown activities. When SCPWRDN is set high, the circuit will deactivate the smart card interface if required and turn off all analog functions and the V_{DD} supply for the logic and companion circuits. The default state upon application of power is the "OFF" state unless power is supplied to the V_{BUS} supply. Note that at any time, the firmware may assert SCPWRDN and the

73S1210F will go into the "OFF" state (when V_{BUS} is not present). If the ON/OFF switch function is not desired and the application does not need to shut down power on VDD, the ON_OFF input can be permanently grounded which will automatically turn on VDD when power is supplied on any of the VPC, VBAT or VBUS power supply inputs.

If power is applied to both V_{BAT} and V_{BUS}, the circuit will automatically consume power from only the V_{BUS} source. The 73S1210F will be unconditionally "ON" when V_{BUS} is applied. If the V_{BUS} source is removed, the 73S1210F will switchover to the VBAT input supply and remain in the "ON" state. The firmware should assert SCPWRDN based on no activity or V_{BUS} removal to reduce battery power consumption. When operating from V_{BUS}, and not calling for V_{CC}, the step-up converter becomes a simple switch connecting V_{BUS} to V_P in order to save power.

Note: When the ON_OFF switch function is not needed, i.e. when the 73S1210F must be in an always-ON state when using another supply than VBUS (V_{PC} or V_{BAT}), some external discrete components are needed.

1.7.4 Power Control Modes

The 73S1210F contains circuitry to disable portions of the device and place it into a lower power standby mode or power down the 73S1210F into its "OFF" mode. The standby mode will stop the core, clock subsystem and the peripherals connected to it. This is accomplished by either shutting off the power or disabling the clock going to the block. The Miscellaneous Control registers MISCtl0, MISCtl1 and the Master Clock Control register (MCLKCtl) provide control over the power modes. The PWRDN bit in MISCtl0 will setup the 73S1210F for standby or "OFF" modes. Depending on the state of the ON/OFF circuitry and power applied to the VBUS input, the 73S1210F will go into either standby mode or power "OFF" mode. If system power is provided by, VBUS or the ON/OFF circuitry is in the "ON" state, the MPU core will placed into standby mode. If the VBUS input is not sourcing power and the ON/OFF circuitry is in the "OFF" state, setting the PWRDN bit will shut down the converter and VP will turn off. The power down mode should only be initiated by setting the PWRDN bit in the MISCtl0 register and not by manipulating individual control bits in various registers. Figure 6 shows how the PWRDN bit controls the various functions that comprise power down state.

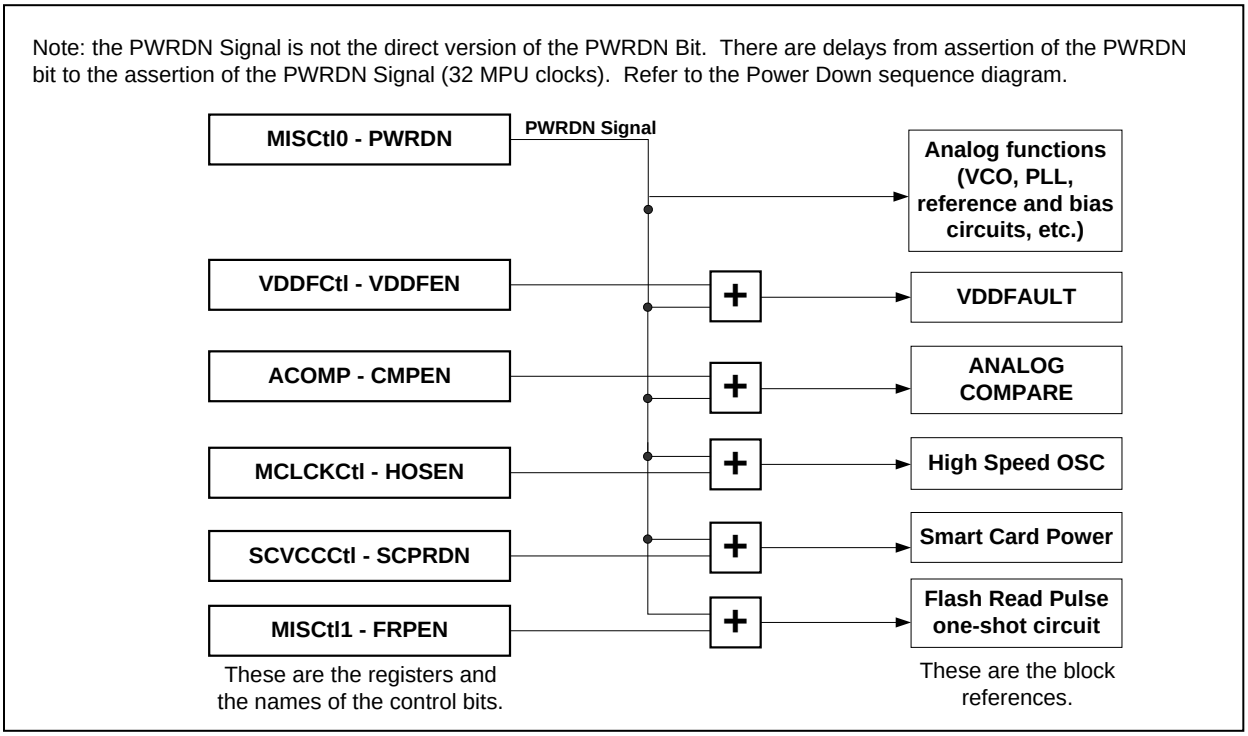

Figure 6: Power Down Control

When the PWRDN bit is set, the clock subsystem will provide a delay of 32 MPUCLK cycles to allow the program to set the STOP bit in the PCON register. This delay will enable the program to properly halt the core before the analog circuits shut down (high speed oscillator, VCO/PLL, voltage reference and bias circuitry, etc.). The PDMUX bit in SFR INT5Ctl should be set prior to setting the PWRDN bit in order to configure the wake up interrupt logic. The power down mode is de-asserted by any of the interrupts connected to external interrupts 0, 4 and 5 (external USR[0:7], smart card and Keypad). These interrupt sources are OR'ed together and routed through some delay logic into INT0 to provide this functionality. The interrupt will turn on the power to all sections that were shut off and start the clock subsystem. After the clock subsystem clocks start running, the MPUCLK begins to clock a 512 count delay counter. When the counter times out, the interrupt will then be active on INT0 and the program can resume. Figure 7 shows the detailed logic for waking up the 73S1210F from a power down state using these specific interrupt sources. Figure 8 shows the timing associated with the power down mode.

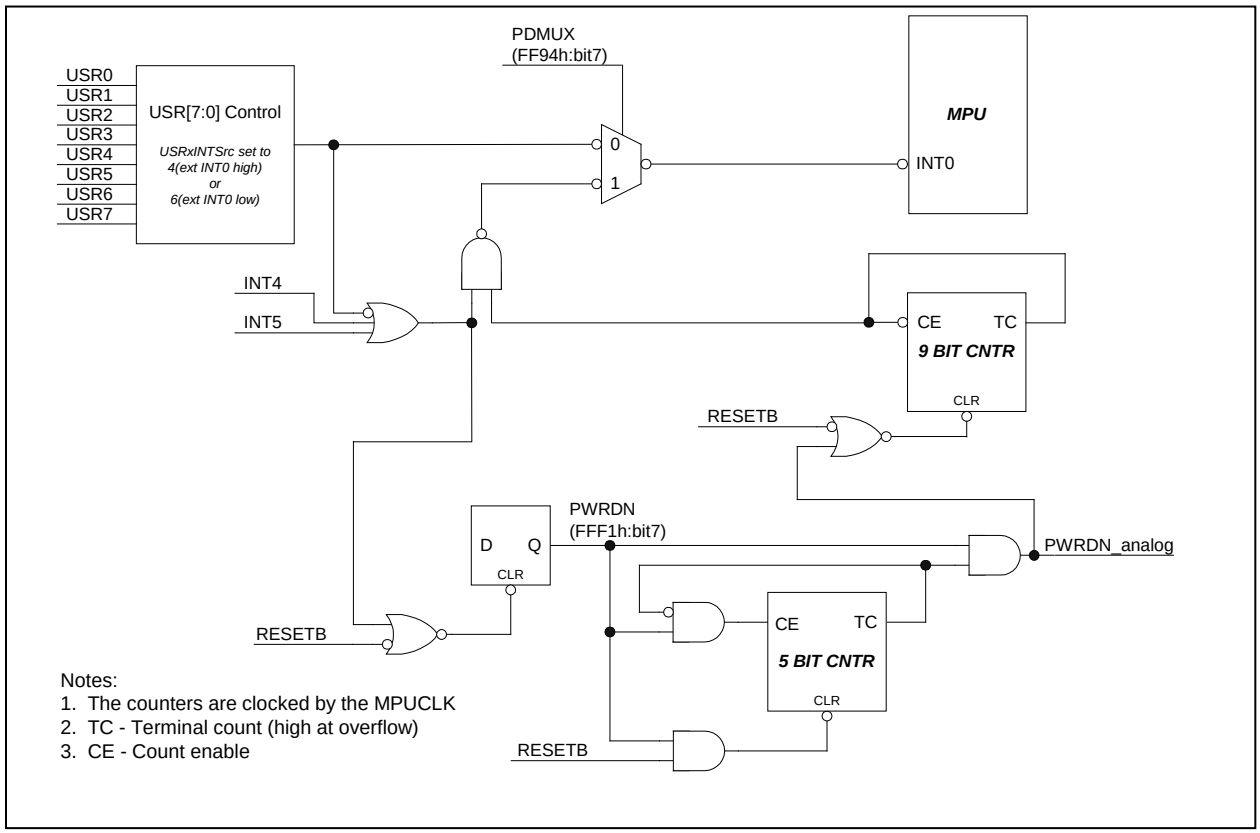

Figure 7: Detail of Power Down Interrupt Logic

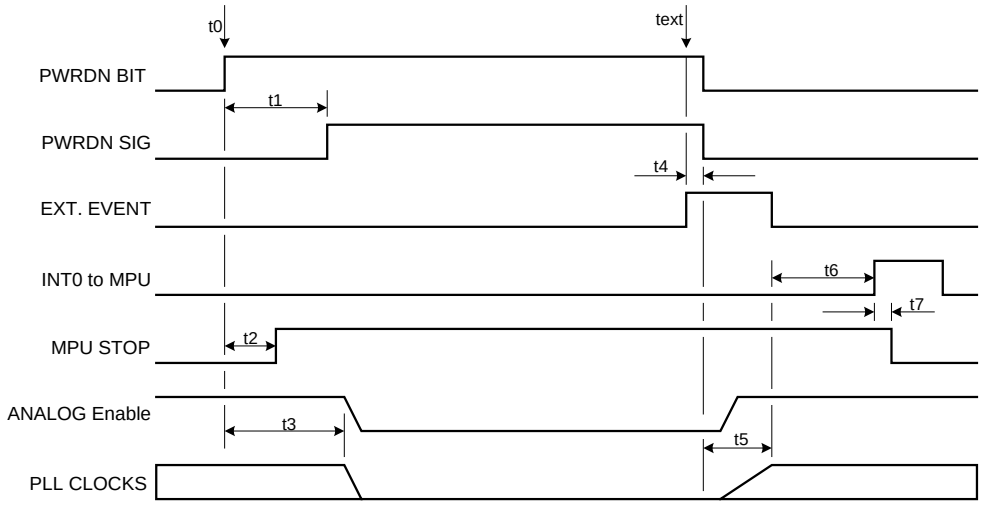

t0: MPU sets PWRDN bit.

t1: 32 MPU clock cycles after t0, the PWRDN SIG is asserted, turning all analog functions OFF.

t2: MPU executes STOP instruction, must be done prior to t1.

t3: Analog functions go to OFF condition. No Vref, PLL/VCO, Ibias, etc.

text: An external event (RTC, Keypad, Card event, USB) occurs.

t4: PWRDN bit and PWRDN signal are cleared by external event.

t5: High-speed oscillator/PLL/VCO operating.

t6: After 512 MPU clock cycles, INT0 to MPU is asserted.

t7: INT0 causes MPU to exit STOP condition.

Figure 8: Power Down Sequencing

External Interrupt Control Register (INT5Ctl): 0xFF94 ← 0x00

Table 14: The INT5Ctl Register

MSB							LSB
PDMUX	–	–	–	–	–	KPIEN	KPINT

Bit	Symbol	Function
INT5Ctl.7	PDMUX	When set = 1, enables interrupts from Keypad (normally going to int5), Smart Card interrupts (normally going to int4), or USR(7:0) pins (int0) to cause interrupt on int0. The assertion of the interrupt to int0 is delayed by 512 MPU clocks to allow the analog circuits, including the clock system, to stabilize. This bit must be set prior to asserting the PWRDN bit in order to properly configure the interrupts that will wake up the circuit. This bit is reset = 0 when this register is read.
INT5Ctl.6	–	
INT5Ctl.5	–	
INT5Ctl.4	–	
INT5Ctl.3	–	
INT5Ctl.2	–	
INT5Ctl.1	KPIEN	Keypad interrupt enable.
INT5Ctl.0	KPINT	Keypad interrupt flag.

Miscellaneous Control Register 0 (MISCtl0): 0xFFF1 ← 0x00

Table 15: The MISCtl0 Register

MSB							LSB
PWRDN	–	–	–	–	–	SLPBK	SSEL

Bit	Symbol	Function
MISCtl0.7	PWRDN	This bit sets the circuit into a low-power condition. All analog (high-speed oscillator and VCO/PLL) functions are disabled 32 MPU clock cycles after this bit is set = 1. This allows time for the next instruction to set the STOP bit in the PCON register to stop the CPU core. The MPU is not operative in this mode. When set, this bit overrides the individual control bits that otherwise control power consumption.
MISCtl0.6	–	
MISCtl0.5	–	
MISCtl0.4	–	
MISCtl0.3	–	
MISCtl0.2	–	
MISCtl0.1	SLPBK	UART loop back testing mode.
MISCtl0.0	SSEL	Serial port pins select.

Miscellaneous Control Register 1 (MISCtl1): 0xFFF2 ← 0x10

Table 16: The MISCtl1 Register

MSB							LSB
–	–	FRPEN	FLSH66	–	–	–	–

Bit	Symbol	Function
MISCtl1.7	–	
MISCtl1.6	–	
MISCtl1.5	FRPEN	Flash Read Pulse enable (low). If FRPEN = 1, the Flash Read signal is passed through with no change. When FRPEN = 0 a one-shot circuit that shortens the Flash Read signal is enabled to save power. The Flash Read pulse will shorten to 40 or 66ns (approximate based on the setting of the FLSH66 bit) in duration, regardless of the MPU clock rate. For MPU clock frequencies greater than 10MHz, this bit should be set high.
MISCtl1.4	FLSH66	When high, creates a 66ns Flash read pulse, otherwise creates a 40ns read pulse when FRPEN is set.
MISCtl1.3	–	
MISCtl1.2	–

PCON.6	–	
PCON.5	–	
PCON.4	–	
PCON.3	GF1	General purpose flag 1.
PCON.2	GF0	General purpose flag 1.
PCON.1	STOP	Sets CPU to Stop mode.
PCON.0	IDLE	Sets CPU to Idle mode.

1.7.5 Interrupts

The 80515 core provides 10 interrupt sources with four priority levels. Each source has its own request flag(s) located in a special function register (TCON, IRCON, and SCON). Each interrupt requested by the corresponding flag can be individually enabled or disabled by the enable bits in SFRs IEN0, IEN1, and IEN2. Some of the 10 sources are multiplexed in order to expand the number of interrupt sources. These are described in more detail in the respective sections.

External interrupts are the interrupts external to the 80515 core, i.e. signals that originate in other parts of the 73S1210F, for example the USR I/O, smart card interface, analog comparators, etc. The external interrupt configuration is shown in Figure 9.

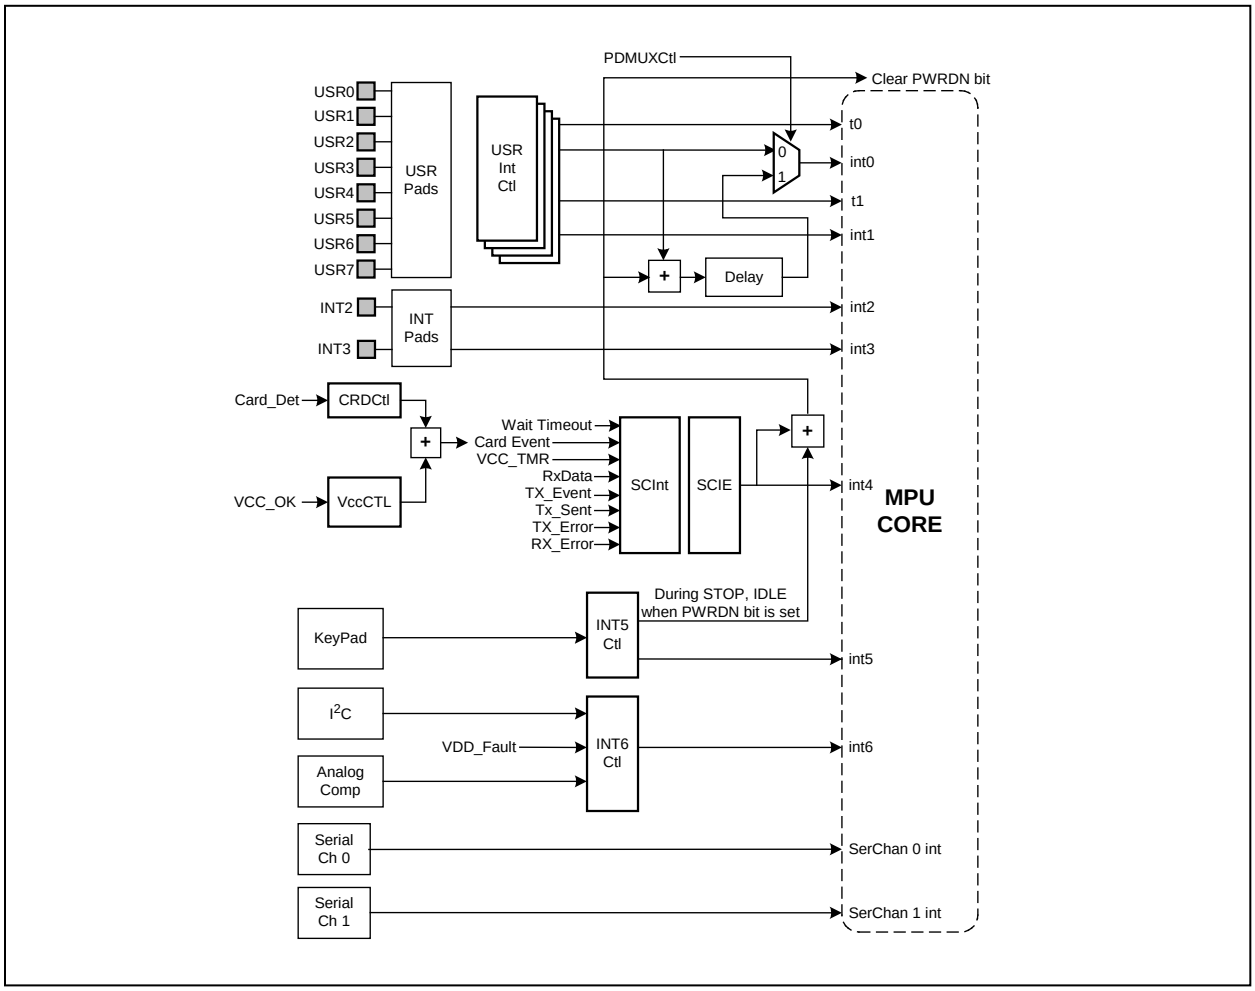

Figure 9: External Interrupt Configuration

1.7.5.1 Interrupt Overview

When an interrupt occurs, the MPU will vector to the predetermined address as shown in Table 32. Once the interrupt service has begun, it can only be interrupted by a higher priority interrupt. The interrupt service is terminated by a return from the RETI instruction. When a RETI is performed, the processor will return to the instruction that would have been next when the interrupt occurred.

When the interrupt condition occurs, the processor will also indicate this by setting a flag bit. This bit is set regardless of whether the interrupt is enabled or disabled. Each interrupt flag is sampled once per machine cycle, then samples are polled by the hardware. If the sample indicates a pending interrupt when the interrupt is enabled, then the interrupt request flag is set. On the next instruction cycle, the interrupt will be acknowledged by hardware forcing an LCALL to the appropriate vector address.

Interrupt response will require a varying amount of time depending on the state of the MPU when the interrupt occurs. If the MPU is performing an interrupt service with equal or greater priority, the new interrupt will not be invoked. In other cases, the response time depends on the current instruction. The fastest possible response to an interrupt is 7 machine cycles. This includes one machine cycle for detecting the interrupt and six cycles to perform the LCALL.

1.7.5.2 Special Function Registers for Interrupts

Interrupt Enable 0 Register (IEN0): 0xA8 ← 0x00

Table 19: The IEN0 Register

MSB							LSB
EAL	WDT	–	ES0	ET1	EX1	ET0	EX0

Bit	Symbol	Function
IEN0.7	EAL	EAL = 0 – disable all interrupts.
IEN0.6	WDT	Not used for interrupt control.
IEN0.5	–	
IEN0.4	ES0	ES0 = 0 – disable serial channel 0 interrupt.
IEN0.3	ET1	ET1 = 0 – disable timer 1 overflow interrupt.
IEN0.2	EX1	EX1 = 0 – disable external interrupt 1.
IEN0.1	ET0	ET0 = 0 – disable timer 0 overflow interrupt.
IEN0.0	EX0	EX0 = 0 – disable external interrupt 0.

Interrupt Enable 1 Register (IEN1): 0xB8 ← 0x00

Table 20: The IEN1 Register

MSB							LSB
–	SWDT	EX6	EX5	EX4	EX3	EX2	–

Bit	Symbol	Function
IEN1.7	–	
IEN1.6	SWDT	Not used for interrupt control.
IEN1.5	EX6	EX6 = 0 – disable external interrupt 6.
IEN1.4	EX5	EX5 = 0 – disable external interrupt 5.
IEN1.3	EX4	EX4 = 0 – disable external interrupt 4.
IEN1.2	EX3	EX3 = 0 – disable external interrupt 3.
IEN1.1	EX2	EX2 = 0 – disable external interrupt 2.
IEN1.0	–	

Interrupt Enable 2 Register (IEN2): 0x9A ← 0x00

Table 21: The IEN2 Register

MSB							LSB
–	–	–	–	–	–	–	ES1

IRCON.3	IEX4	External interrupt 4 flag.
IRCON.2	IEX3	External interrupt 3 flag.
IRCON.1	IEX2	External interrupt 2 flag.
IRCON.0	–	

1.7.5.3 External Interrupts

The external interrupts (external to the CPU core) are connected as shown in Table 25. Interrupts with multiple sources are OR'ed together and individual interrupt source control is provided in XRAM SFRs to mask the individual interrupt sources and provide the corresponding interrupt flags. Multifunction USR [7:0] pins control Interrupts 0 and 1. Dedicated external interrupt pins INT2 and INT3 control interrupts 2 and 3. The polarity of interrupts 2 and 3 is programmable in the MPU. Interrupts 4, 5 and 6 have multiple peripheral sources and are multiplexed to one of these three interrupts. The peripheral functions will be described in subsequent sections. Generic 80515 MPU literature states that interrupts 4 through 6 are defined as rising edge sensitive. Thus, the hardware signals attached to interrupts 4, 5 and 6 are converted to rising edge level by the hardware.

SFR (special function register) enable bits must be set to permit any of these interrupts to occur. Likewise, each interrupt has its own flag bit that is set by the interrupt hardware and is reset automatically by the MPU interrupt handler.

Table 25: External MPU Interrupts

External Interrupt	Connection	Polarity	Flag Reset
0	USR I/O High Priority	see USRIntCtlx	Automatic
1	USR I/O Low Priority	see USRIntCtlx	Automatic
2	External Interrupt Pin INT2	Edge selectable	Automatic
3	External Interrupt Pin INT3	Edge selectable	Automatic
4	Smart Card Interrupts	N/A	Automatic
5	Keypad	N/A	Automatic
6	I^2C, V_{DD}_Fault, Analog Comp	N/A	Automatic

Note: Interrupts 4, 5 and 6 have multiple interrupt sources and the flag bits are cleared upon reading of the corresponding register. To prevent any interrupts from being ignored, the register containing multiple interrupt flags should be stored temporary to allow each interrupt flag to be tested separately to see which interrupt(s) is/are pending.

Table 26: Control Bits for External Interrupts

Enable Bit	Description
EX0	Enable external interrupt 0
EX1	Enable external interrupt 1
EX2	Enable external interrupt 2
EX3	Enable external interrupt 3
EX4	Enable external interrupt 4
EX5	Enable external interrupt 5
EX6	Enable external interrupt 6

Flag Bit	Description
IE0	External interrupt 0 flag
IE1	External interrupt 1 flag
IEX2	External interrupt 2 flag
IEX3	External interrupt 3 flag
IEX4	External interrupt 4 flag
IEX5	External interrupt 5 flag
IEX6	External interrupt 6 flag

1.7.5.4 Power Down Interrupt Logic

The 73S1210F contains special interrupt logic to allow INT0 to wake up the CPU from a power down (CPU STOP) state. See the Power Control Modes section for details.

1.7.5.5 Interrupt Priority Level Structure

All interrupt sources are combined in groups, as shown in Table 27.

Table 27: Priority Level Groups

Group			
0	External interrupt 0	Serial channel 1 interrupt	
1	Timer 0 interrupt	–	External interrupt 2
2	External interrupt 1	–	External interrupt 3
3	Timer 1 interrupt	–	External interrupt 4
4	Serial channel 0 interrupt	–	External interrupt 5
5	–	–	External interrupt 6

Each group of interrupt sources can be programmed individually to one of four priority levels by setting or clearing one bit in the special function register IP0 and one in IP1. If requests of the same priority level are received simultaneously, an internal polling sequence as per Table 31 determines which request is serviced first.

IEN enable bits must be set to permit any of these interrupts to occur. Likewise, each interrupt has its own flag bit that is set by the interrupt hardware and is reset automatically by the MPU interrupt handler.

Interrupt Priority 0 Register (IP0): 0xA9 ← 0x00

Table 28: The IP0 Register

MSB LSB

IEX4	External interrupt 4	0x005B
IEX5	External interrupt 5	0x0063
IEX6	External interrupt 6	0x006B

1.7.6 UART

The 80515 core of the 73S1210F includes two separate UARTs that can be programmed to communicate with a host. The 73S1210F can only connect one UART at a time since there is only one set of TX and Rx pins. The MISCtl0 register is used to select which UART is connected to the TX and RX pins. Each UART has a different set of operating modes that the user can select according to their needs. The UART is a dedicated 2-wire serial interface, which can communicate with an external host processor at up to 115,200 bits/s. The TX and RX pins operate at the V_{DD} supply voltage levels and should never exceed 3.6V. The operation of each pin is as follows:

RX: Serial input data is applied at this pin. Conforming to RS-232 standard, the bytes are input LSB first. The voltage applied at RX must not exceed 3.6V.

TX: This pin is used to output the serial data. The bytes are output LSB first.

The 73S1210F has several UART-related read/write registers. All UART transfers are programmable for parity enable, parity select, 2 stop bits/1 stop bit and XON/XOFF options for variable communication baud rates from 300 to 115200 bps. Table 33 shows the selectable UART operation modes and Table 34 shows how the baud rates are calculated.

Table 33: UART Modes

	UART 0	UART 1
Mode 0	N/A	Start bit, 8 data bits, parity, stop bit, variable baud rate (internal baud rate generator).
Mode 1	Start bit, 8 data bits, stop bit, variable baud rate (internal baud rate generator or timer 1).	Start bit, 8 data bits, stop bit, variable baud rate (internal baud rate generator).
Mode 2	Start bit, 8 data bits, parity, stop bit, fixed baud rate 1/32 or 1/64 of $f_{CKMPU.}$	N/A
Mode 3	Start bit, 8 data bits, parity, stop bit, variable baud rate (internal baud rate generator or timer 1).	N/A

Note: Parity of serial data is available through the P flag of the accumulator. Seven-bit serial modes with parity, such as those used by the FLAG protocol, can be simulated by setting and reading bit 7 of 8-bit output data. Seven-bit serial modes without parity can be simulated by setting bit 7 to a constant 1. 8-bit serial modes with parity can be simulated by setting and reading the 9th bit, using the control bits S0CON3 and S1CON3 in the S0COn and S1CON SFRs.

Table 34: Baud Rate Generation

	Using Timer 1	Using Internal Baud Rate Generator
Serial Interface 0	$2^{smod} * f_{CKMPU}/ (384 * (256-TH1))$	$2^{smod} * f_{CKMPU}/(64 * (2^{10}-S0REL))$
Serial Interface 1	N/A	$f_{CKMPU}/(32 * (2^{10}-S1REL))$

Note: S0REL (9:0) and S1REL (9:0) are 10-bit values derived by combining bits from the respective timer reload registers SxRELH (bits 1:0) and SxRELL (bits 7:0). TH1 is the high byte of timer 1. The SMOD bit is located in the PCON SFR.

Power Control Register 0 (PCON): 0x87 ← 0x00

The SMOD bit used for the baud rate generator is set up via this register.

Table 35: The PCON Register

MSB							LSB
SMOD	–	–	–	GF1	GF0	STOP	IDLE

Bit	Symbol	Function
PCON.7	SMOD	If SM0D = 1, the baud rate is doubled.
PCON.6	–	
PCON.5	–	
PCON.4	–	
PCON.3	GF1	General purpose flag 1.
PCON.2	GF0	General purpose flag 1.
PCON.1	STOP	Sets CPU to Stop mode.
PCON.0	IDLE	Sets CPU to Idle mode.

Baud Rate Control Register 0 (BRCON): 0xD8 ← 0x00

The BSEL bit used to enable the baud rate generator is set up via this register.

Table 36: The BRCON Register

MSB							LSB
BSEL	–	–	–	–	–	–	–

Bit	Symbol	Function
BRCON.7	BSEL	If BSEL = 0, the baud rate is derived using timer 1. If BSEL = 1 the baud rate generator circuit is used.
BRCON.6	–	
BRCON.5	–	.
BRCON.4	–	
BRCON.3	–	
BRCON.2	–	
BRCON.1	–	
BRCON.0	–	

Miscellaneous Control Register 0 (MISCtl0): 0xFFF1 ← 0x00

Transmit and receive (TX and RX) pin selection and loop back test configuration are setup via this register.

Table 37: The MISCtl0 Register

MSB							LSB
PWRDN	–	–	–	–	–	SLPBK	SSEL

Bit	Symbol	Function
MISCtl0.7	PWRDN	This bit places the 73S1210F into a power down state.
MISCtl0.6	–	
MISCtl0.5	–	
MISCtl0.4	–	
MISCtl0.3	–	
MISCtl0.2	–	
MISCtl0.1	SLPBK	1 = UART loop back testing mode. The pins TXD and RXD are to be connected together externally (with SLPBK =1) and therefore: SLPBK SSEL Mode 0 0 normal using Serial_0 0 1 normal using Serial_1 1 0 Serial_0 TX feeds Serial_1 RX 1 1 Serial_1 TX feeds Serial_0 RX
MISCtl0.0	SSEL	Selects either Serial_1 if set =1 or Serial_0 if set = 0 to be connected to RXD and TXD pins.

1.7.6.1 Serial Interface 0

The Serial Interface 0 can operate in 4 modes:

- **Mode 0**

  Pin RX serves as input and output. TX outputs the shift clock. 8 bits are transmitted with LSB first. The baud rate is fixed at 1/12 of the crystal frequency. Reception is initialized in Mode 0 by setting the flags in S0CON as follows: RI0 = 0 and REN0 = 1. In other modes, a start bit when REN0 = 1 starts receiving serial data.

- **Mode 1**

  Pin RX serves as input, and TX serves as serial output. No external shift clock is used, 10 bits are transmitted: a start bit (always 0), 8 data bits (LSB first), and a stop bit (always 1). On receive, a start bit synchronizes the transmission, 8 data bits are available by reading S0BUF, and stop bit sets the flag RB80 in the Special Function Register S0CON. In mode 1 either internal baud rate generator or timer 1 can be use to specify baud rate.

- **Mode 2**

  This mode is similar to Mode 1, with two differences. The baud rate is fixed at 1/32 or 1/64 of oscillator frequency and 11 bits are transmitted or received: a start bit (0), 8 data bits (LSB first), a programmable 9th bit, and a stop bit (1). The 9th bit can be used to control the parity of the serial interface: at transmission, bit TB80 in S0CON is output as the 9th bit, and at receive, the 9th bit affects RB80 in Special Function Register S0CON.

- **Mode 3**
  The only difference between Mode 2 and Mode 3 is that in Mode 3 either internal baud rate generator or timer 1 can be use to specify baud rate.

The S0BUF register is used to read/write data to/from the serial 0 interface.

Serial Interface 0 Control Register (S0CON): 0x9B ← 0x00

Transmit and receive data are transferred via this register.

Table 38: The S0CON Register

MSB LSB

SM0	SM1	SM20	REN0	TB80	RB80	TI0	RI0

Bit	Symbol	Function
S0CON.7	SM0	These two bits set the UART0 mode:
S0CON.6	SM1	
S0CON.5	SM20	Enables the inter-processor communication feature.
S0CON.4	REN0	If set, enables serial reception. Cleared by software to disable reception.
S0CON.3	TB80	The 9th transmitted data bit in Modes 2 and 3. Set or cleared by the MPU, depending on the function it performs (parity check, multiprocessor communication etc.).
S0CON.2	RB80	In Modes 2 and 3 it is the 9th data bit received. In Mode 1, if SM20 is 0, RB80 is the stop bit. In Mode 0 this bit is not used. Must be cleared by software.
S0CON.1	TI0	Transmit interrupt flag, set by hardware after completion of a serial transfer. Must be cleared by software.
S0CON.0	RI0	Receive interrupt flag, set by hardware after completion of a serial reception. Must be cleared by software.

Mode	Description	SM0	SM1
0	N/A	0	0
1	8-bit UART	0	1
2	9-bit UART	1	0
3	9-bit UART	1	1

1.7.6.2 Serial Interface 1

The Serial Interface 1 can operate in 2 modes:

- **Mode A**

  This mode is similar to Mode 2 and 3 of Serial interface 0, 11 bits are transmitted or received: a start bit (0), 8 data bits (LSB first), a programmable 9th bit, and a stop bit (1). The 9th bit can be used to control the parity of the serial interface: at transmission, bit TB81 in S1CON is outputted as the 9th bit, and at receive, the 9th bit affects RB81 in Special Function Register S1CON. The only difference between Mode 3 and A is that in Mode A only the internal baud rate generator can be use to specify baud rate.

- **Mode B**

  This mode is similar to Mode 1 of Serial interface 0. Pin RX serves as input, and TX serves as serial output. No external shift clock is used, 10 bits are transmitted: a start bit (always 0), 8 data bits (LSB first), and a stop bit (always 1). On receive, a start bit synchronizes the transmission, 8 data bits are available by reading S1BUF, and stop bit sets the flag RB81 in the Special Function Register S1CON. In mode 1, the internal baud rate generator is use to specify the baud rate.

The S1BUF register is used to read/write data to/from the serial 1 interface.

Serial Interface Control Register (S1CON): 0x9B ← 0x00

The function of the serial port depends on the setting of the Serial Port Control Register S1CON.

Table 39: The S1CON Register

MSB LSB

SM	–	SM21	REN1	TB81	RB81	TI1	RI1

Bit	Symbol	Function
S1CON.7	SM	Sets the UART operation mode. SM=0: Mode A, 9-bit UART, variable baud rate SM=1: Mode B, 8-bit UART, variable baud rate
S1CON.6	–	
S1CON.5	SM21	Enables the inter-processor communication feature.
S1CON.4	REN1	If set, enables serial reception. Cleared by software to disable reception.
S1CON.3	TB81	The 9th transmitted data bit in Mode A. Set or cleared by the MPU, depending on the function it performs (parity check, multiprocessor communication, etc.).
S1CON.2	RB81	In Mode B, if sm21 is 0, rb81 is the stop bit. Must be cleared by software.
S1CON.1	TI1	Transmit interrupt flag, set by hardware after completion of a serial transfer. Must be cleared by software.
S1CON.0	RI1	Receive interrupt flag, set by hardware after completion of a serial reception. Must be cleared by software.

Multiprocessor operation mode: The feature of receiving 9 bits in Modes 2 and 3 of Serial Interface 0 or in Mode A of Serial Interface 1 can be used for multiprocessor communication. In this case, the slave processors have bit SM20 in S0CON or SM21 in S1CON set to 1. When the master processor outputs slave's address, it sets the 9th bit to 1, causing a serial port receive interrupt in all the slaves. The slave processors compare the received byte with their network address. If there is a match, the addressed slave will clear SM20 or SM21 and receive the rest of the message, while other slaves will leave the SM20 or SM21 bit unaffected and ignore this message. After addressing the slave, the host will output the rest of the message with the 9th bit set to 0, so no serial port receive interrupt will be generated in unselected slaves.

1.7.7 Timers and Counters

The 80515 has two 16-bit timer/counter registers: Timer 0 and Timer 1. These registers can be configured for counter or timer operations.

In timer mode, the register is incremented every machine cycle, meaning that it counts up after every 12 periods of the MPU clock signal.

In counter mode, the register is incremented when the falling edge is observed at the corresponding input signal T0 or T1 (T0 and T1 are the timer gating inputs derived from USR[0:7] pins, see the User (USR) Ports section). Since it takes 2 machine cycles to recognize a 1-to-0 event, the maximum input count rate is 1/2 of the oscillator frequency. There are no restrictions on the duty cycle, however to ensure proper recognition of 0 or 1 state, an input should be stable for at least 1 machine cycle.

Four operating modes can be selected for Timer 0 and Timer 1. Two Special Function Registers (TMOD and TCON) are used to select the appropriate mode.

The Timer 0 load registers are designated as TL0 and TH0 and the Timer 1 load registers are designated as TL1 and TH1.

Timer/Counter Mode Control Register (TMOD): 0x89 ← 0x00

Table 40: The TMOD Register

MSB LSB

GATE	C/T	M1	M0	GATE	C/T	M1	M0
Timer 1				**Timer 0**			

Bits TR1 and TR0 in the TCON register start their associated timers when set.

Bit	Symbol	Function
TMOD.7 TMOD.3	Gate	If set, enables external gate control (USR pin(s) connected to T0 or T1 for Counter 0 or 1, respectively). When T0 or T1 is high, and TRx bit is set (see the TCON register), a counter is incremented every falling edge on T0 or T1 input pin. If not set, the TRx bit controls the corresponding timer.
TMOD.6 TMOD.2	C/T	Selects Timer or Counter operation. When set to 1, the counter operation is performed based on the falling edge of T0 or T1. When cleared to 0, the corresponding register will function as a timer.
TMOD.5 TMOD.1	M1	Selects the mode for Timer/Counter 0 or Timer/Counter 1, as shown in the TMOD description.
TMOD.4 TMOD.0	M0	Selects the mode for Timer/Counter 0 or Timer/Counter 1, as shown in the TMOD description.

Table 41: Timers/Counters Mode Description

M1	M0	Mode	Function
0	0	Mode 0	13-bit Counter/Timer.
0	1	Mode 1	16-bit Counter/Timer.
1	0	Mode 2	8-bit auto-reload Counter/Timer.
1	1	Mode 3	If Timer 1 M1 and M0 bits are set to '1', Timer 1 stops. If Timer 0 M1 and M0 bits are set to '1', Timer 0 acts as two independent 8-bit Timer/Counters.

Mode 0

Putting either timer/counter into mode 0 configures it as an 8-bit timer/counter with a divide-by-32 prescaler. In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all 1's to all 0's, it sets the timer overflow flag TF0. The overflow flag TF0 then can be used to request an interrupt. The counted input is enabled to the timer when TRx = 1 and either GATE = 0 or TX = 1 (setting GATE = 1 allows the timer to be controlled by external input TX, to facilitate pulse width measurements). TRx are control bits in the special function register TCON; GATE is in TMOD. The 13-bit register consists of all 8 bits of TH1 and the lower 5 bits of TL0. The upper 3 bits of TL0 are indeterminate and should be ignored. Setting the run flag (TRx) does not clear the registers. Mode 0 operation is the same for timer 0 as for timer 1.

Mode 1

Mode 1 is the same as mode 0, except that the timer register is run with all 16 bits.

Mode 2

Mode 2 configures the timer register as an 8-bit counter (TLx) with automatic reload. The overflow from TLx not only sets TFx, but also reloads TLx with the contents of THx, which is preset by software. The reload leaves THx unchanged.

Mode 3

Mode 3 has different effects on timer 0 and timer 1. Timer 1 in mode 3 simply holds its count. The effect is the same as setting TR1 = 0. Timer 0 in mode 3 establishes TL0 and TH0 as two separate counters. TL0 uses the timer 0 control bits: C/T, GATE, TR0, INT0, and TF0. TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from timer 1. Thus, TH0 now controls the "timer 1" interrupt. Mode 3 is provided for applications requiring an extra 8-bit timer or counter. When timer 0 is in mode 3, timer 1 can be turned on and off by switching it out of and into its own mode 3, or can still be used by the serial channel as a baud rate generator, or in fact, in any application not requiring an interrupt from timer 1 itself.

Timer/Counter Control Register (TCON): 0x88 ← 0x00

Table 42: The TCON Register

MSB LSB

TF1	TR1	TF0	TR0	IE1	IT1	IE0	IT0

Bit	Symbol	Function
TCON.7	TF1	Timer 1 overflow flag.
TCON.6	TR1	Not used for interrupt control.
TCON.5	TF0	Timer 0 overflow flag.
TCON.4	TR0	Not used for interrupt control.
TCON.3	IE1	Interrupt 1 edge flag is set by hardware when the falling edge on external interrupt int1 is observed. Cleared when an interrupt is processed.
TCON.2	IT1	Interrupt 1 type control bit. 1 selects falling edge and 0 selects low level for input pin to cause an interrupt.
TCON.1	IE0	Interrupt 0 edge flag is set by hardware when the falling edge on external interrupt int0 is observed. Cleared when an interrupt is processed.
TCON.0	IT0	Interrupt 0 type control bit. 1 selects falling edge and 0 sets low level for input pin to cause interrupt.

1.7.8 WD Timer (Software Watchdog Timer)

The software watchdog timer is a 16-bit counter that is incremented once every 24 or 384 clock cycles. After a reset, the watchdog timer is disabled and all registers are set to zero. The watchdog consists of a 16-bit counter (WDT), a reload register (WDTREL), prescalers (by 2 and by 16), and control logic. Once the watchdog starts, it cannot be stopped unless the internal reset signal becomes active.

WD Timer Start Procedure: The WDT is started by setting the SWDT flag. When the WDT register enters the state 0x7CFF, an asynchronous WDTS signal will become active. The signal WDTS sets bit 6 in the IP0 register and requests a reset state. WDTS is cleared either by the reset signal or by changing the state of the WDT timer.

Refreshing the WD Timer: The watchdog timer must be refreshed regularly to prevent the reset request signal from becoming active. This requirement imposes an obligation on the programmer to issue two instructions. The first instruction sets WDT and the second instruction sets SWDT. The maximum delay allowed between setting WDT and SWDT is 12 clock cycles. If this period has expired and SWDT has not been set, WDT is automatically reset, otherwise the watchdog timer is reloaded with the content of the WDTREL register and WDT is automatically reset.

Interrupt Enable 0 Register (IEN0): 0xA8 ← 0x00

Table 43: The IEN0 Register

MSB							LSB
EAL	WDT	ET2	ES0	ET1	EX1	ET0	EX0

Bit	Symbol	Function
IEN0.7	EAL	EAL = 0 – disable all interrupts.
IEN0.6	WDT	Watchdog timer refresh flag. Set to initiate a refresh of the watchdog timer. Must be set directly before SWDT is set to prevent an unintentional refresh of the watchdog timer. WDT is reset by hardware 12 clock cycles after it has been set.
IEN0.5	–	
IEN0.4	ES0	ES0 = 0 – disable serial channel 0 interrupt.
IEN0.3	ET1	ET1 = 0 – disable timer 1 overflow interrupt.
IEN0.2	EX1	EX1 = 0 – disable external interrupt 1.
IEN0.1	ET0	ET0 = 0 – disable timer 0 overflow interrupt.
IEN0.0	EX0	EX0 = 0 – disable external interrupt 0.

Interrupt Enable 1 Register (IEN1): 0xB8 ← 0x00

Table 44: The IEN1 Register

MSB							LSB
–	SWDT	EX6	EX5	EX4	EX3	EX2	–

Bit	Symbol	Function
IEN1.7	–	
IEN1.6	SWDT	Watchdog timer start/refresh flag. Set to activate/refresh the watchdog timer. When directly set after setting WDT, a watchdog timer refresh is performed. Bit SWDT is reset by the hardware 12 clock cycles after it has been set.
IEN1.5	EX6	EX6 = 0 – disable external interrupt 6.
IEN1.4	EX5	EX5 = 0 – disable external interrupt 5.
IEN1.3	EX4	EX4 = 0 – disable external interrupt 4.
IEN1.2	EX3	EX3 = 0 – disable external interrupt 3.
IEN1.1	EX2	EX2 = 0 – disable external interrupt 2.
IEN1.0	–	

Interrupt Priority 0 Register (IP0): 0xA9 ← 0x00

Table 45: The IP0 Register

MSB							LSB
–	WDTS	IP0.5	IP0.4	IP0.3	IP0.2	IP0.1	IP0.0

Bit	Symbol	Function
IP0.6	WDTS	Watchdog timer status flag. Set when the watchdog timer has expired. The internal reset will be generated, but this bit will not be cleared by the reset. This allows the user program to determine if the watchdog timer caused the reset to occur and respond accordingly. Can be read and cleared by software.

Note: The remaining bits in the IP0 register are not used for watchdog control.

Watchdog Timer Reload Register (WDTREL): 0x86 ← 0x00

Table 46: The WDTREL Register

MSB							LSB
WDPSEL	WDREL6	WDREL5	WDREL4	WDREL3	WDREL2	WDREL1	WDREL0

Bit	Symbol	Function
WDTREL.7	WDPSEL	Prescaler select bit. When set, the watchdog is clocked through an additional divide-by-16 prescaler.
WDTREL.6 to WDTREL.0	WDREL6-0	Seven bit reload value for the high-byte of the watchdog timer. This value is loaded to the WDT when a refresh is triggered by a consecutive setting of bits WDT and SWDT.

1.7.9 User (USR) Ports

The 73S1210F includes 8 pins of general purpose digital I/O (GPIO). On reset or power-up, all USR pins are inputs until they are configured for the desired direction. The pins are configured and controlled by the USR70 and UDIR70 SFRs. Each pin declared as USR can be configured independently as an input or output with the bits of the UDIR70 register. Table 47 lists the direction registers and configurability associated with each group of USR pins. USR pins 0 to 7 are multiple use pins that can be used for general purpose I/O, external interrupts and timer control. Table 48 shows the configuration for a USR pin through its associated bit in its UDIR register. Values read from and written into the GPIO ports use the data registers USR70. Note: After reset, all USR pins are defaulted as inputs and pulled up to VDD until any write to the corresponding UDIR register is performed. This insures all USR pins are set to a known value until set by the firmware. Unused USR pins can be set for output if unused and unconnected to prevent them from floating. Alternatively, unused USR pins can be set for input and tied to ground or V_{DD}.

Table 47: Direction Registers and Internal Resources for DIO Pin Groups

USR Pin Group	Type	Direction Register Name	Direction Register (SFR) Location	Data Register Name	Data Register (SFR) Location
USR_0…USR_7	Multi-use	UDIR70	0x91 [7:0]	USR70	0x90 [7:0]

Table 48: UDIR Control Bit

	UDIR Bit	
	0	1
USR Pin Function	output	input

Four XRAM SFR registers (USRIntTCtl0, USRIntTCtl1, USRIntTCtl2, and USRIntTCtl3) control the use of the USR [7:0] pins. Each of the USR [7:0] pins can be configured as GPIO or individually be assigned an internal resource such as an interrupt or a timer/counter control. Each of the four registers contains two 3-bit configuration words named UxIS (where x corresponds to the USR pin). The control resources selectable for the USR pins are listed in Table 50 through Table 53. If more than one input is connected to the same resource, the resources are combined using a logical OR.

Table 49: Selectable Controls Using the UxIS Bits

UxIS Value	Resource Selected for USRx Pin
0	None
1	None
2	T0 (counter0 gate/clock)
3	T1 (counter1 gate/clock)
4	Interrupt 0 rising edge/high level on USRx
5	Interrupt 1 rising edge/high level on USRx
6	Interrupt 0 falling edge/low level on USRx
7	Interrupt 1 falling edge/low level on USRx

Note: x denotes the corresponding USR pin. Interrupt edge or level control is assigned in the IT0 and IT1 bits in the TCON register.

External Interrupt Control Register (USRIntCtl1) : 0xFF90 ← 0x00

1.7.10 Analog Voltage Comparator

The 73S1210F includes a programmable comparator that is connected to the ANA_IN pin. The comparator can be configured to trigger an interrupt if the input voltage rises above or falls below a selectable threshold voltage. The comparator control register should not be modified when the analog interrupt (ANAIEN bit in the INT6Ctl register) is enabled to guard against any false interrupt that might be generated when modifying the threshold. The comparator has a built-in hysteresis to prevent the comparator from repeatedly responding to low-amplitude noise. This hysteresis is approximately 20mV. Interrupt control is handled in the INT6Ctl register.

Analog Compare Control Register (ACOMP): 0xFFD0 ← 0x00

Table 54: The ACOMP Register

MSB LSB

ANALVL	–	ONCHG	CPOL	CMPEN	TSEL.2	TSEL.1	TSEL.0

Bit	Symbol	Function
ACOMP.7	ANALVL	When read, indicates whether the input level is above or below the threshold. This is a real time value and is not latched, so it may change from the time of the interrupt trigger until read.
ACOMP.6	–	
ACOMP.5	ONCHG	If set, the Ana_interrupt is invoked on any change above or below the threshold, bit 4 is ignored.
ACOMP.4	CPOL	If set = 1, Ana_interrupt is invoked when signal rises above selected threshold. If set = 0, Ana_interrupt is invoked when signal goes below selected threshold (default).
ACOMP.3	CMPEN	Enables power to the analog comparator. 1 = Enabled. 0 = Disabled (default).
ACOMP.2	TSEL.2	Sets the voltage threshold for comparison to the voltage on pin ANA_IN. Thresholds are as follows: TSEL.2 TSEL.1 TSEL.0 Voltage Threshold 0 0 0 1.00V 0 0 1 1.24V 0 1 0 1.40V 0 1 1 1.50V 1 0 0 1.75V 1 0 1 2.00V 1 1 0 2.30V 1 1 1 2.50V

INT6Ctl.3	I2CIEN	I^2C interrupt enabled.
INT6Ctl.2	I2CINT	I^2C interrupt flag.
INT6Ctl.1	ANIEN	If ANIEN = 1 Analog Compare event interrupt is enabled. When masked (ANIEN = 0), ANINT (bit 0) may be set, but no interrupt is generated.
INT6Ctl.0	ANINT	(Read Only) Set when the selected ANA_IN signal changes with respect to the selected threshold if Compare_Enable is asserted. Cleared on read of register.

1.7.11 LED Driver

The 73S1210F provides a single dedicated output pin for driving an LED. The LED driver pin can be configured as a current source that will pull to ground to drive an LED that is connected to VDD without the need for an external current limiting resistor. This pin may be used as general purpose output with the programmed pull-down current and a strong (CMOS) pull-up, if enabled. The analog block must be enabled when this output is being used to drive the selected output current.

This pin may be used as an input with consideration of the programmed output current and level. The register bit when read, indicates the state of the pin.

LED Control Register (LEDCtl): 0xFFF3 ← 0xFF

Table 56: The LEDCtl Register

LEDCtl.6	LPUEN	0 = Pull-ups are enabled for all of the LED pins.
LEDCtl.5	ISET.1	These two bits control the drive current (to ground) for the LED driver pin. Current levels are: 00 = 0ma(off) 01 = 2ma 10 = 4ma 11 = 10ma
LEDCtl.4	ISET.0	
LEDCtl.3	–	
LEDCtl.2	–	
LEDCtl.1	–	
LEDCtl.0	LEDD0	Write data controls output level of pin LED0. Read will report level of pin LED0.

1.7.12 I²C Master Interface

The 73S1210F includes a dedicated fast mode, 400kHz I²C Master interface. The I²C interface can read or write 1 or 2 bytes of data per data transfer frame. The MPU communicates with the interface through six dedicated SFR registers:

- Device Address (DAR)
- Write Data (WDR)
- Secondary Write Data (SWDR)
- Read Data (RDR)
- Secondary Read Data (SRDR)
- Control and Status (CSR)

The DAR register is used to set up the slave address and specify if the transaction is a read or write operation. The CSR register sets up, starts the transaction and reports any errors that may occur. When the I²C transaction is complete, the I²C interrupt is reported via external interrupt 6. The I²C interrupt is automatically de-asserted when a subsequent I²C transaction is started. The I²C interface uses a 400kHz clock from the time-base circuits.

1.7.12.1 I²C Write Sequence

To write data on the I²C Master Bus, the 80515 has to program the following registers according to the following sequence:

1. Write slave device address to Device Address register (DAR). The data contains 7 bits for the slave device address and 1 bit of op-code. The op-code bit should be written with a 0 to indicate a write operation.
2. Write data to Write Data register (WDR). This data will be transferred to the slave device.
3. If writing 2 bytes, set bit 0 of the Control and Status register (CSR) and load the second data byte to Secondary Write Data register (SWDR).
4. Set bit 1 of the CSR register to start I²C Master Bus.
5. Wait for I²C interrupt to be asserted. It indicates that the write on I²C Master Bus is done. Refer to information about the INT6Ctl, IEN1 and IRCON register for masking and flag operation.

Figure 10 shows the timing of the I²C write mode:

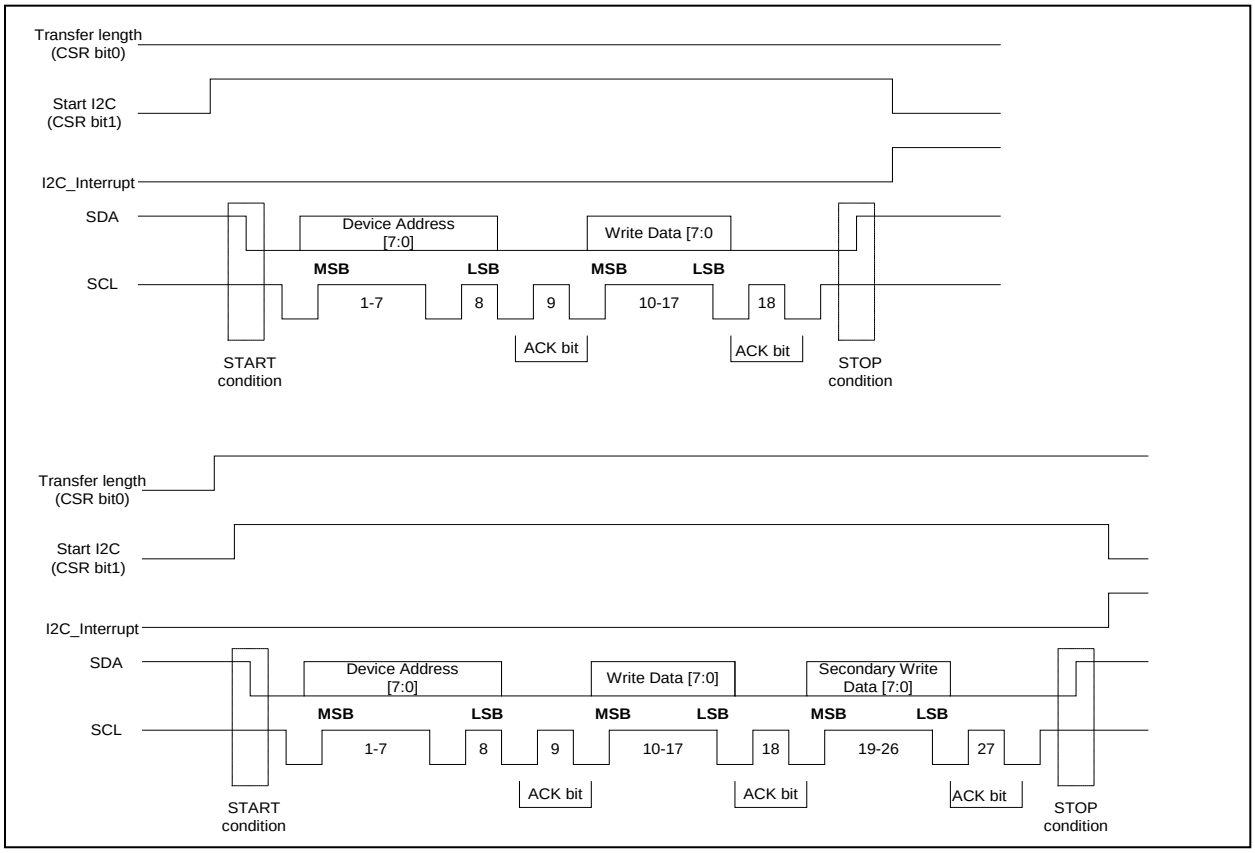

Figure 10: I²C Write Mode Operation

1.7.12.2 I²C Read Sequence

To read data on the I²C Master Bus from a slave device, the 80515 has to program the following registers in this sequence:

1. Write slave device address to Device Address register (DAR). The data contains 7 bits device address and 1 bit of op-code. The op-code bit should be written with a 1.
2. Write control data to Control and Status register. Write a 1 to bit 1 to start I²C Master Bus. Also write a 1 to bit 0 if the Secondary Read Data register (SRDR) is to be captured from the I²C Slave device.
3. Wait for I²C interrupt to be asserted. It indicates that the read operation on the I²C bus is done. Refer to information about the INT6Ctl, IEN1 and IRCON registers for masking and flag operation.
4. Read data from the Read Data register (RDR).
5. Read data from Secondary Read Data register (SRDR) if bit 0 of Control and Status register (CSR) is written with a 1.

Figure 11 shows the timing of the I²C read mode:

INT6Ctl.0	ANINT	Analog compare interrupt flag.

1.7.13 Keypad Interface

The 73S1210F supports a 30-button (6 rows x 5 columns) keypad (SPST Mechanical Contact Switches) interface using 11 dedicated I/O pins. Figure 12 shows a simplified block diagram of the keypad interface.

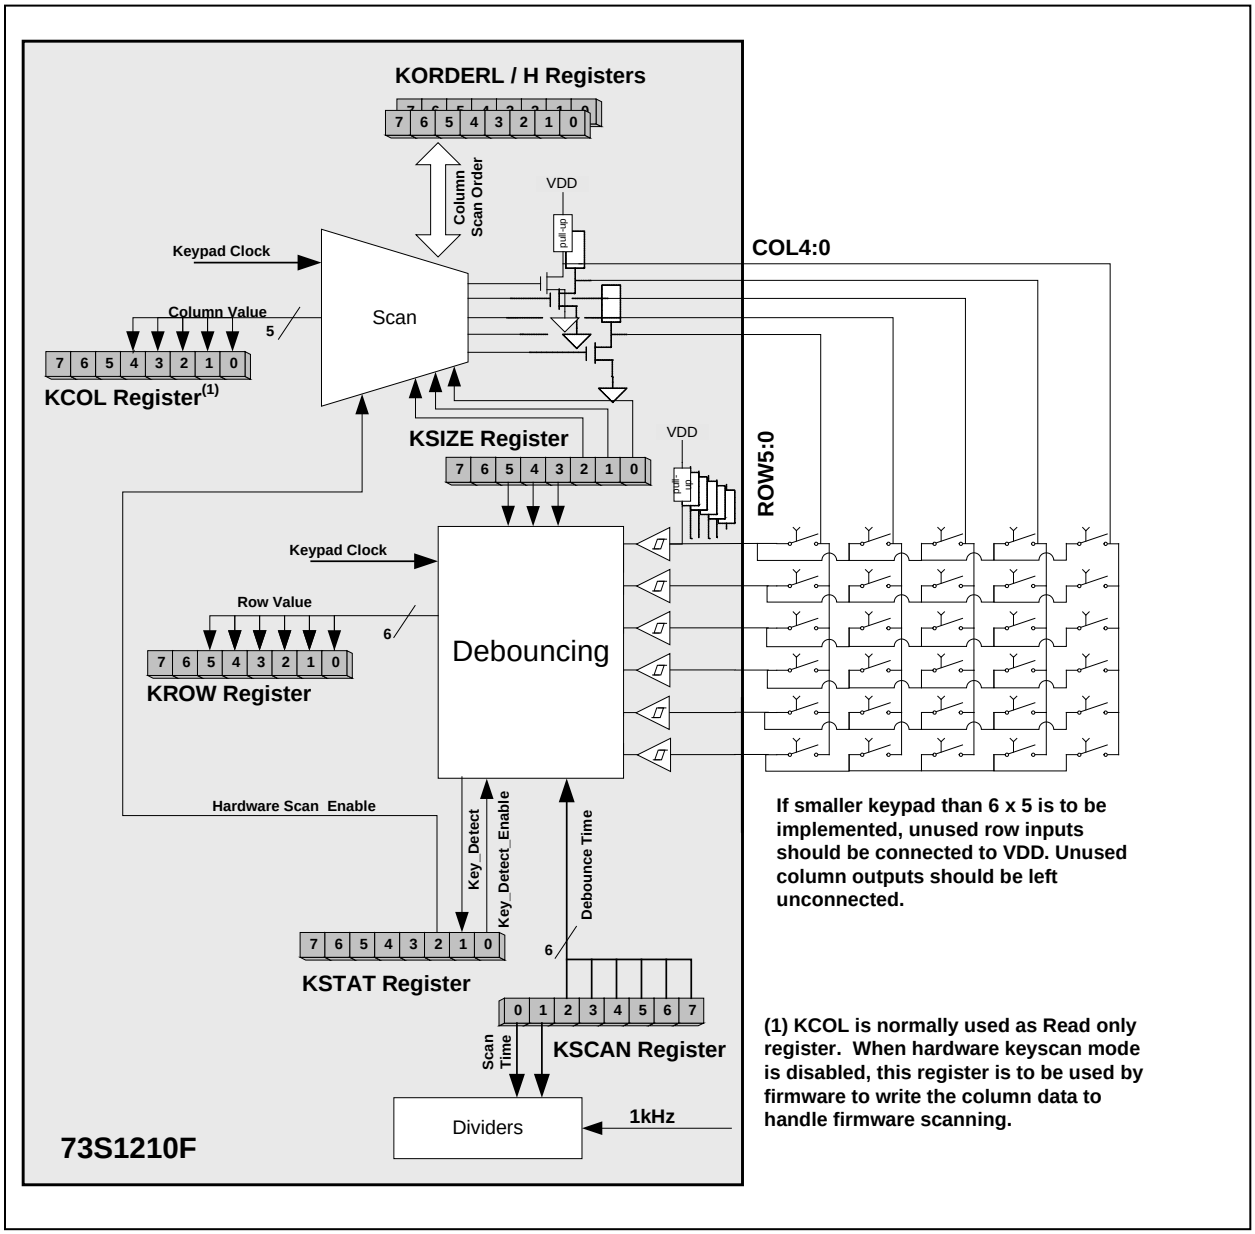

Figure 12: Simplified Keypad Block Diagram

There are five drive lines (outputs) corresponding to columns and 6 sense lines (inputs) corresponding to rows. Hysteresis and pull-ups are provided on all inputs (rows), which eliminate the need for external resistors in the keypad. Key scanning happens by asserting one of the 5 column lines low and looking for a low on a sense line indicating that a key is pressed (switch closed) at the intersection of the drive/sense (column/row) line in the keypad. Key detection is performed by hardware with an incorporated debounce timer. Debouncing time is adjustable through the KSCAN register. Internal hardware circuitry performs column scanning at an adjustable scanning rate and column scanning order through registers KSCAN and KORDERL / KORDERH. Key scanning is disabled at reset and must be enabled by firmware. When a valid key is detected, an interrupt is generated and the valid value of the pressed key is automatically

written into the KCOL and KROW registers. The keypad interface uses a 1kHz clock derived from the 12MHz crystal. The clock is enabled by setting bit 6 – KBEN – in the MCLKCtl register (see the Oscillator and Clock Generation section) to carry out scanning and debouncing. The keypad size can be adjusted within the KSIZE register.

Normal scanning is performed by hardware when the SCNEN bit is set at 1 in the KSTAT register. Figure 13 shows the flowchart of how the hardware scanning operates. In order to minimize power, scanning does not occur until a key-press is detected. Once hardware key scanning is enabled, the hardware drives all column outputs low and waits for a low to be detected on one of the inputs. When a low is detected on any row, and before key scanning starts, the hardware checks that the low level is still detected after a debounce time. The debounce time is defined by firmware in the KSCAN register (bits 7:0, DBTIME). Debounce times from 4ms to 256ms in 4ms increments are supported. If a key is not pressed after the debounce time, the hardware will go back to looking for any input to be low. If a key is confirmed to be pressed, key scanning begins.

Key scanning asserts one of the 5 drive lines (COL 4:0) low and looks for a low on a sense line indicating that a key is pressed at the intersection of the drive/sense line in the keypad. After all sense lines have been checked without a key-press being detected, the next column line is asserted. The time between checking each sense line is the scan time and is defined by firmware in the KSCAN register (bits 0:1 – SCTIME). Scan times from 1ms to 4ms are supported. Scanning order does not affect the scan time. This scanning continues until the entire keypad is scanned. If only one key is pressed, a valid key is detected. Simultaneous key presses are not considered as valid (If two keys are pressed, no key is reported to firmware).

Possible scrambling of the column scan order is provided by means of the KORDERL and KORDERH registers that define the order of column scanning. Values in these registers must be updated every time a new keyboard scan order is desired. It is not possible to change the order of scanning the sense lines. The column and row intersection for the detected valid key are stored in the KCOL and KROW registers. When a valid key is detected, an interrupt is generated. Firmware can then read those registers to determine which key had been pressed. After reading the KCOL and KROW registers, the firmware can update the KORDERL / KORDERH registers if a new scan order is needed. When the SCNEN bit is enabled in the KSTAT register, the KCOL and KROW registers are only updated after a valid key has been identified. The hardware does not wait for the firmware to service the interrupt in order to proceed with the key scanning process. Once the valid key (or invalid key – e.g. two keys pressed) is detected, the hardware waits for the key to be released. Once the key is released, the debounce timer is started. If the key is not still released after the debounce time, the debounce counter starts again. After a key release, all columns will be driven low as before and the process will repeat waiting for any key to be pressed. When the SCNEN bit is disabled, all drive outputs are set to the value in the KCOL register. If firmware clears the SCNEN bit in the middle of a key scan, the KCOL register contains the last value stored in there which will then be reflected on the output pins. A bypass mode is provided so that the firmware can do the key scanning manually (SCNEN bit must be cleared). In bypass mode, the firmware writes/reads the Column and Row registers to perform the key scanning.

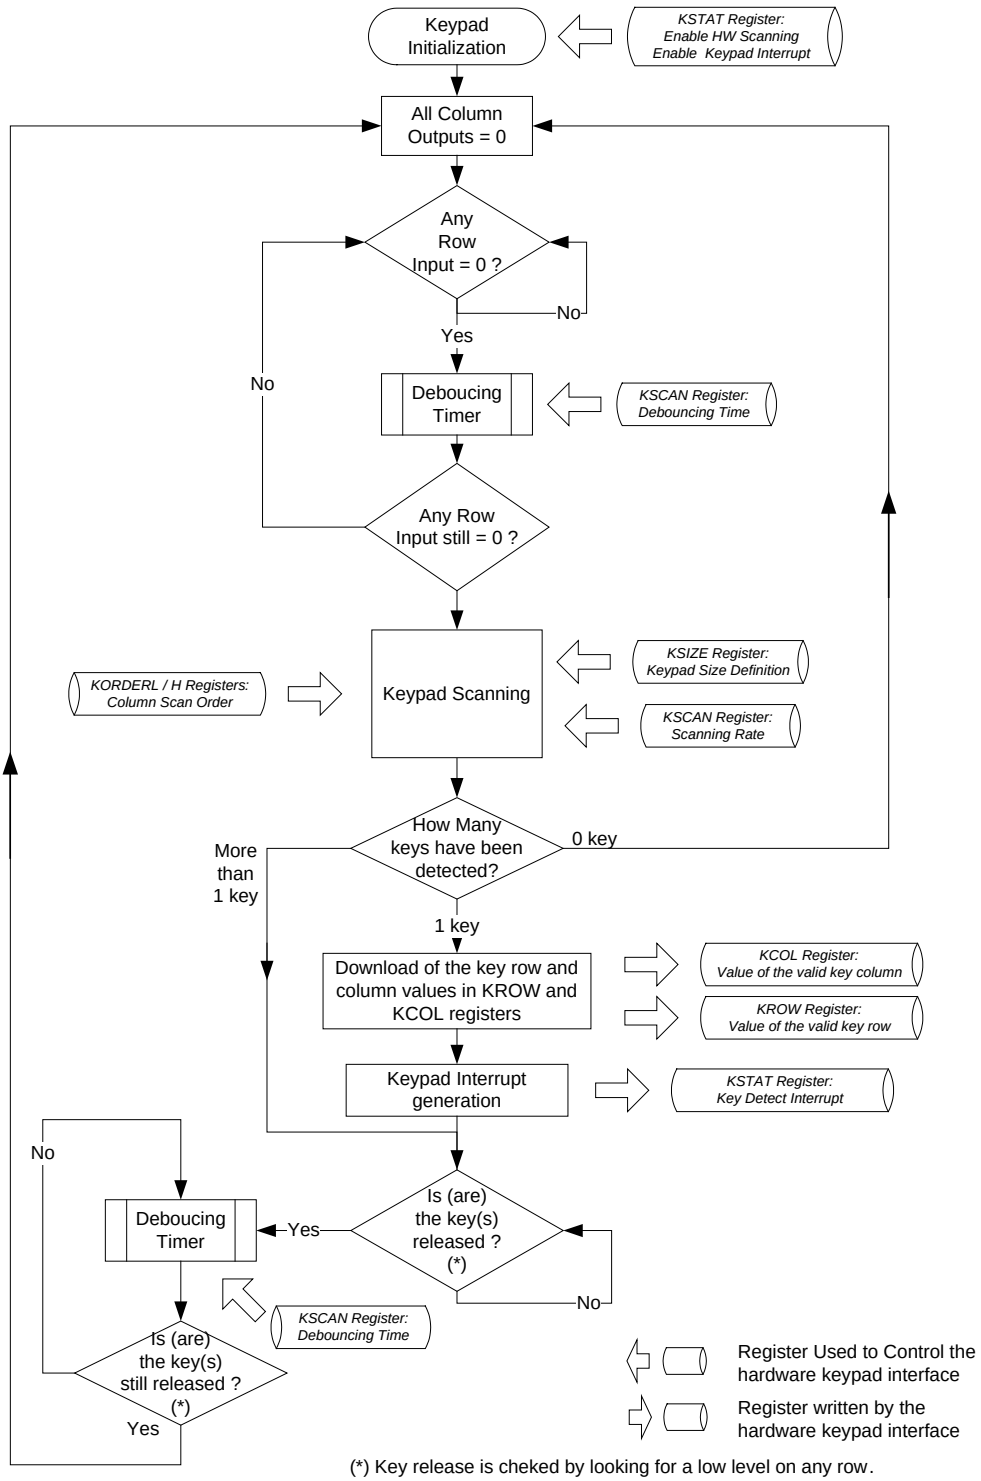

Figure 13: Keypad Interface Flow Chart

Keypad Column Register (KCOL): 0xD1 ← 0x1F

This register contains the value of the column of a key detected as valid by the hardware. In bypass mode, this register firmware writes directly this register to carry out manual scanning.

Table 64: The KCOL Register

MSB							LSB
–	–	–	COL.4	COL.3	COL.2	COL.1	COL.0

Bit	Symbol	Function
KCOL.7	–	
KCOL.6	–	
KCOL.5	–	
KCOL.4	COL.4	Drive lines bit mapped to corresponding with pins COL(4:0). When a key is detected, firmware reads this register to determine column. In bypass (S/W keyscan) mode, Firmware writes this register directly. 0x1E = COL(0) low, all others high. 0x0F = COL(4) low, all others high. 0x1F = COL(4:0) all high.
KCOL.3	COL.3	
KCOL.2	COL.2	
KCOL.1	COL.1	
KCOL.0	COL.0	

Keypad Row Register (KROW): 0xD2 ← 0x3F

This register contains the value of the row of a key detected as valid by the hardware. In bypass mode, this register firmware reads directly this register to carry out manual detection.

Table 65: The KROW Register

MSB							LSB
–	–	ROW.5	ROW.4	ROW.3	ROW.2	ROW.1	ROW.0

Bit	Symbol	Function
KROW.7	–	
KROW.6	–	
KROW.5	ROW.6	Sense lines bit mapped to correspond with pins ROW(5:0). When key detected, firmware reads this register to determine row. In bypass mode, firmware reads rows and has to determine if there was a key press or not. 0x3E = ROW(0) low, all others high. 0x1F = ROW(5) low, all others high. 0x3F = ROW(5:0) all high.
KROW.4	ROW.4	
KROW.3	ROW.3	
KROW.2	ROW.2	
KROW.1	ROW.1	
KROW.0	ROW.0	

Keypad Scan Time Register (KSCAN): 0xD3 ← 0x00

This register contains the values of scanning time and debouncing time.

Table 66: The KSCAN Register

MSB							LSB
DBTIME.5	DBTIME.4	DBTIME.3	DBTIME.2	DBTIME.1	DBTIME.0	SCTIME.1	SCTIME.0

Bit	Symbol	Function
KSCAN.7	DBTIME.5	Debounce time in 4ms increments. 1 = 4ms de-bounce time, 0x3F = 252ms, 0x00 = 256ms. Key presses and key releases are debounced by this amount of time.
KSCAN.6	DBTIME.4	
KSCAN.5	DBTIME.3	
KSCAN.4	DBTIME.2	
KSCAN.3	DBTIME.1	
KSCAN.2	DBTIME.0	
KSCAN.1	SCTIME.1	Scan time in ms. 01 = 1ms, 02 = 2ms, 00 = 3ms, 00 = 4ms. Time between checking each key during keypad scanning.
KSCAN.0	SCTIME.0	

Keypad Control/Status Register (KSTAT): 0xD4 ← 0x00

This register is used to control the hardware keypad scanning and detection capabilities, as well as the keypad interrupt control and status.

Table 67: The KSTAT Register

MSB							LSB
–	–	–	–	KEYCLK	HWSCEN	KEYDET	KYDTEN

Bit	Symbol	Function
KSTAT.7	–	
KSTAT.6	–	
KSTAT.5	–	
KSTAT.4	–	
KSTAT.3	KEYCLK	The current state of the keyboard clock can be read from this bit.
KSTAT.2	HWSCEN	Hardware Scan Enable – When set, the hardware will perform automatic key scanning. When cleared, the firmware must perform the key scanning manually (bypass mode).
KSTAT.1	KEYDET	Key Detect – When HWSCEN = 1, this bit is set causing an interrupt that indicates a valid key press was detected and the key location can be read from the Keypad Column and Row registers. When HWSCEN = 0, this bit is an interrupt which indicates a falling edge on any Row input if all Row inputs had been high previously (note: multiple Key Detect interrupts may occur in this case due to the keypad switch bouncing). In all cases, this bit is cleared when read. When HWSCEN = 0 and the keypad interface 1kHz clock is disabled, a key press will still set this bit and cause an interrupt.
KSTAT.0	KYDTEN	Key Detect Enable – When set, the KEYDET bit can cause an interrupt and when cleared the KEYDET cannot cause an interrupt. KEYDET can still get set even if the interrupt is not enabled.

Keypad Scan Time Register (KSIZE): 0xD5 ← 0x00

This register is not applicable when HWSCEN is not set. Unused row inputs should be connected to VDD.

Table 68: The KSIZE Register

KSIZE.4	ROWSIZ.1	
KSIZE.3	ROWSIZ.0	
KSIZE.2	COLSIZ.2	Defines the number of columns in the keypad. Maximum number is 5 given the number of column pins on the package. Allows for a reduced keypad size for scanning.
KSIZE.1	COLSIZ.1	
KSIZE.0	COLSIZ.0	

Keypad Column LS Scan Order Register (KORDERL): 0xD6 ← 0x00

In the KORDERL and KORDERH registers, Column Scan Order(14:0) is grouped into 5 sets of 3 bits each. Each set determines which column (COL(4:0) pin) to activate by loading the column number into the 3 bits. When in HW_Scan_Enable mode, the hardware will step through the sets from 1Col to 5Col (up to the number of columns in Colsize) and scan the column defined in the 3 bits. To scan in sequential order, set a counting pattern with 0 in set 0, and 1 in set 1,and 2 in set 2, and 3 in set 3, and 4 in set 4. The firmware should update this as part of the interrupt service routine so that the new scan order is loaded prior to the next key being pressed. For example, to scan COL(0) first, 1Col(2:0) should be loaded with 000'b. To scan COL(4) fifth, 5Col(2:0) should be loaded with 100'b.

Table 69: The KORDERL Register

MSB							LSB
3COL.1	3COL.0	2COL.2	2COL.1	2COL.0	1COL.2	1COL.1	1COL.0

Bit	Symbol	Function
KORDERL.7	3COL.1	Column to scan 3rd (lsb's).
KORDERL.6	3COL.0	
KORDERL.5	2COL.2	Column to scan 2nd.
KORDERL.4	2COL.1	
KORDERL.3	2COL.0	
KORDERL.2	1COL.2	Column to scan 1st.
KORDERL.1	1COL.1	
KORDERL.0	1COL.0

INT5Ctl.1	KPIEN	Enables Keypad interrupt when set = 1.
INT5Ctl.0	KPINT	This bit indicates the Keypad logic has set Key_Detect bit and a key location may be read. Cleared on read of register.

1.7.14 Emulator Port

The emulator port, consisting of the pins E_RST, E_TCLK and E_RXTX, provides control of the MPU through an external in-circuit emulator. The E_TBUS[3:0] pins, together with the E_ISYNC/BRKRQ, add trace capability to the emulator. The emulator port is compatible with the ADM51 emulators manufactured by Signum Systems™.

The signals of the emulator port have weak pull-ups. Adding resistor footprints for signals E_RST, E_TCLK and E_RXTX on the PCB is recommended. If necessary, adding 10kΩ pull-up resistors on E_TCLK and E_RXTX and a 3kΩ on E_RST will help the emulator operate normally if a problem arises. If code trace capability is needed on this interface, 20pF capacitors ((to ground) need to be added to allow the trace function capability to run properly. These capacitors should be attached to the TBUS0:3 and ISBR signals.

1.7.15 Smart Card Interface Function

The 73S1210F integrates one ISO-7816 (T=0, T=1) UART, one complete ICC electrical interface as well as an external smart card interface to allow multiple smart cards to be connected using the Teridian 8010 family of interface devices. Figure 14 shows the simplified block diagram of the card circuitry (UART + interfaces), with detail of dedicated XRAM registers.

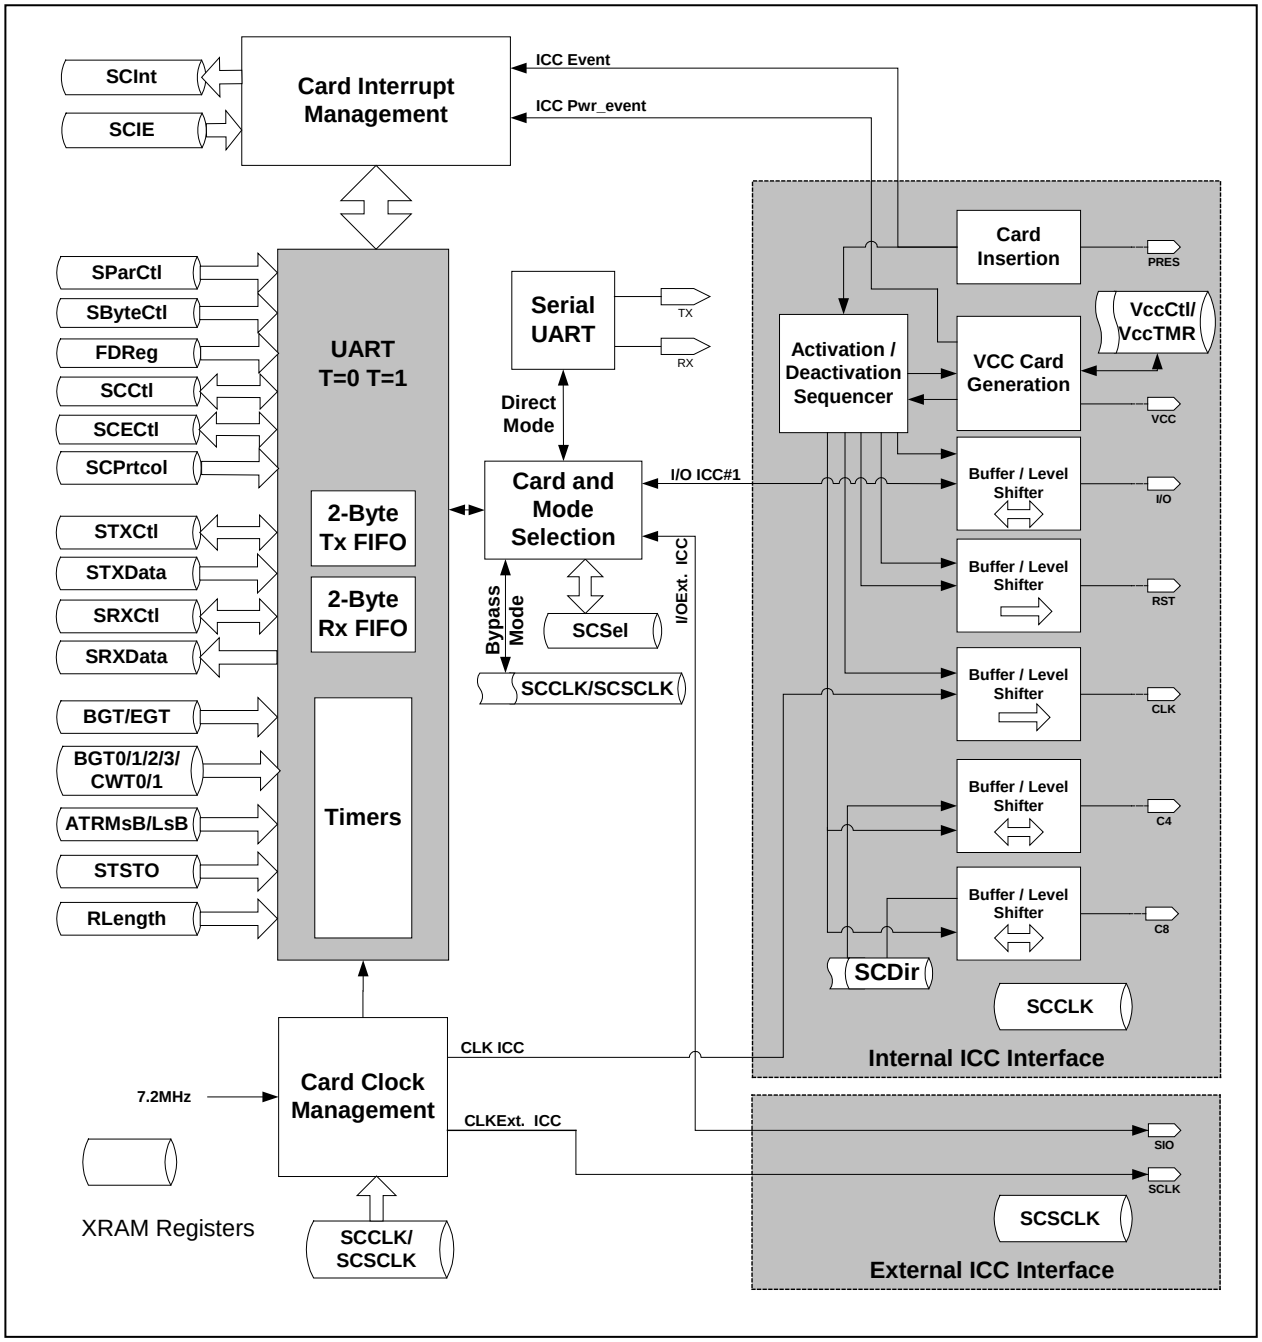

Figure 14: Smart Card Interface Block Diagram

Card interrupts are managed through two dedicated registers: SCIE (Interrupt Enable to define which interrupt is enabled) and SCInt (Interrupt status). They allow the firmware to determine the source of an interrupt, that can be a card insertion / removal, card power fault, or a transmission (TX) or reception (RX) event / fault. It should be noted that even when card clock is disabled, an ICC interrupt can be generated

on a card insertion / removal to allow power saving modes. Card insertion / removal is generated from the respective card switch detection inputs (whose polarity is programmable).

The built-in ICC Interface has a linear regulator (V_{CC} generator) capable of driving 1.8, 3.0 and 5.0V smart cards in accordance with the ISO 7816-3 and EMV4.1 standards. This converter uses the V_P (5.5V nominal) input supply source. See the power supply management section above for more detail. Auxiliary I/O lines C4 and C8 are only provided for the built-in interface. If support for the auxiliary lines is necessary for the external smart card interface, they need to be handled manually through the USR GPIO pins. The external 73S8010x devices directly connect the I/O (SIO) and clock (SCLK) signals and control is handled via the I^2C interface.

Figure 15 shows how multiple 8010 devices can be connected to the 73S1210F.

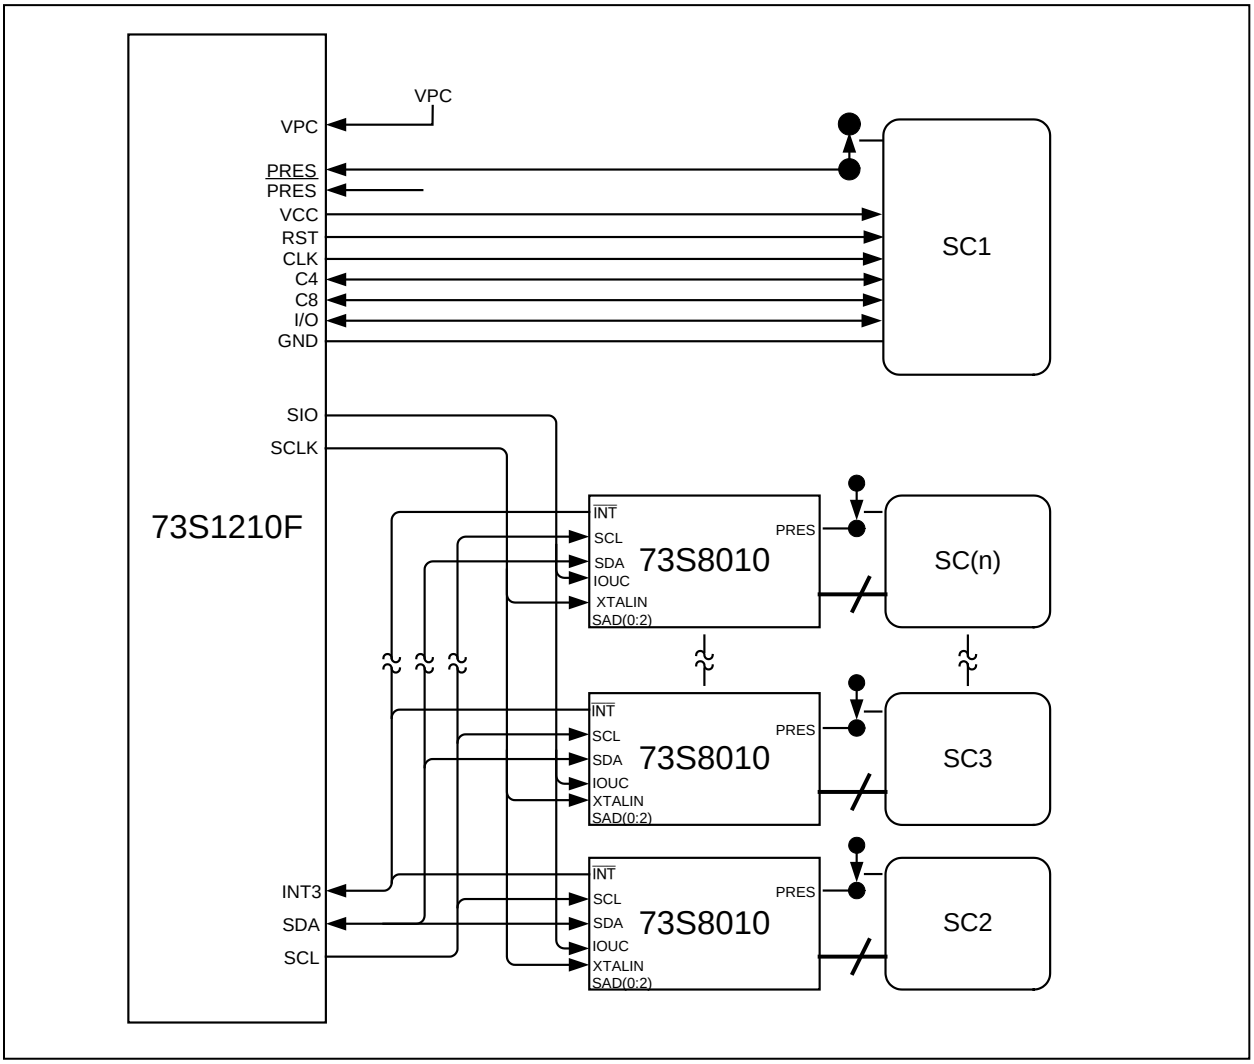

Figure 15: External Smart Card Interface Block Diagram

1.7.15.1 ISO 7816 UART

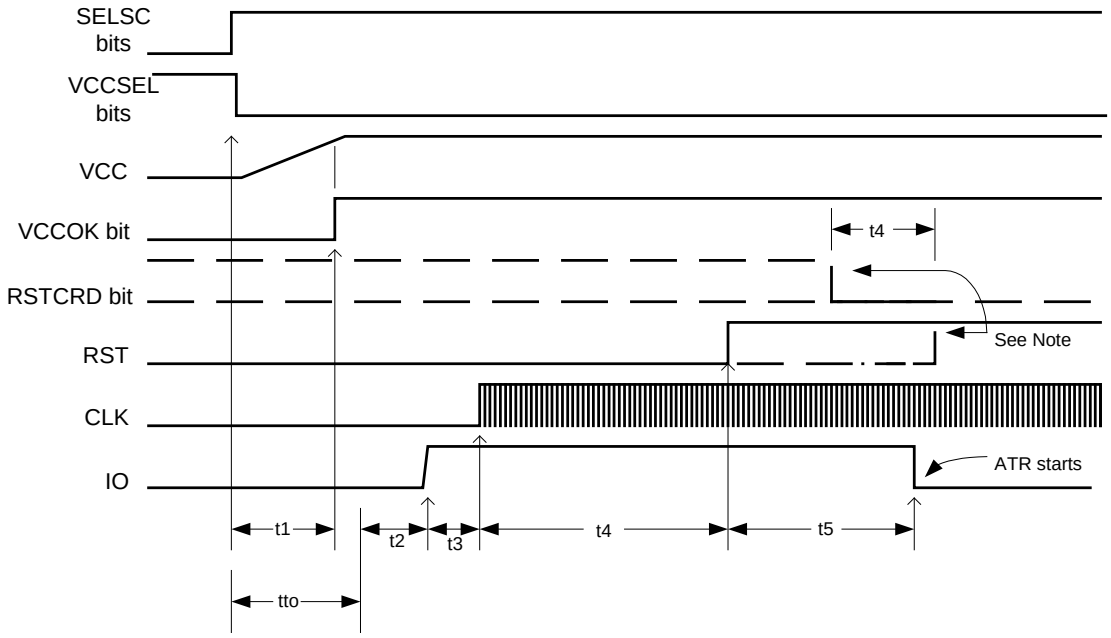
An embedded ISO 7816 (hardware) UART is provided to control communications between a smart card and the 73S1210F MPU. The UART can be shared between the one built-in ICC interface and the external ICC interface. Selection of the desired interface is made by register SCSel. Control of the external interface is handled by the I^2C interface for any external 73S8010x device. The following is a list of features for the ISO 7816 UART:

- Two-byte FIFO for temporary data storage on both TX and Rx data.
- Parity checking in T=0. This feature can be enabled/disabled by firmware. Parity error reporting to firmware and Break generation to ICC can be controlled independently.
- Parity error generation for test purposes.
- Retransmission of last byte if ICC indicates T=0 parity error. This feature can be enabled/disabled by firmware.
- Deletion of last byte received if ICC indicates T=0 parity error. This feature can be enabled/disabled by firmware.
- CRC/LRC generation and checking. CRC/LRC is automatically inserted into T=1 data stream by the hardware. This feature can be enabled/disabled by firmware.
- Support baud rates: 115200, 57600, 38400, 28800, 19200, 14400, 9600 under firmware control (assuming 12MHz crystal) with various F/D settings.
- Firmware manages F/D. All F/D combinations are supported in which F/D is directly divisible by 31 or 32 (i.e. F/D is a multiple of either 31 or 32).
- Flexible ETU clock generation and control.
- Detection of convention (direct or indirect) character TS. This affects both polarity and order of bits in byte. Convention can be overridden by firmware.
- Supports WTX Timeout with an expanded Wait Time Counter (28 bits).
- A Bypass Mode is provided to bypass the hardware UART in order for the software to emulate the UART (for non-standard operating modes). In such a case, the I/O line value is reflected in SFR SCCtl or SCECtl respectively for the built-in or external interfaces. This mode is appropriate for some synchronous and non T=0 / T=1 cards.

The single integrated smart card UART is capable of supporting T=0 and T=1 cards in hardware therefore offloading the bit manipulation tasks from the firmware. The embedded firmware instructs the hardware which smart card it should communicate with at any point in time. Firmware reconfigures the UART as required when switching between smart cards. When the 73S1210F has transmitted a message with an expected response, the firmware should not switch the UART to another smart card until the first smart card has responded. If the smart card responds while another smart card is selected, that first smart card's response will be ignored.

1.7.15.2 Answer to Reset Processing

A card insertion event generates an interrupt to the firmware, which is then responsible for the configuration of the electrical interface, the UART and activation of the card. The activation sequencer goes through the power up sequence as defined in the ISO 7816-3 specification. An asynchronous activation timing diagram is shown in
Figure 16. After the card reset is de-asserted, the firmware instructs the hardware to look for a TS byte that begins the ATR response. If a response is not provided within the pre-programmed timeout period, an interrupt is generated and the firmware can then take appropriate action, including instructing the 73S1210F to begin a deactivation sequence. Once commanded, the deactivation sequencer goes through the power down sequence as defined in the ISO 7816-3 specification. If an ATR response is received, the hardware looks for a TS byte that determines direct/inverse convention. The hardware handles the indirect convention conversion such that the embedded firmware only receives direct convention. This feature can be disabled by firmware within SByteCtl register. Parity checking and break generation is performed on the TS byte unless disabled by firmware. If during the card session, a card removal, over-current or other error event is detected, the hardware will automatically perform the deactivation sequence and then generate an interrupt to the firmware. The firmware can then perform any other error handling required for proper system operation. Smart card RST, I/O and CLK, C4, C8 shall be low before the end of the deactivation sequence. Figure 17 shows the timing for a deactivation sequence.



t1: SELSC.1 bit set (selects internal ICC interface) and a non-zero value in VCCSEL bits (calling for a value of Vcc of 1.8, 3.0, or 5.0 volts) will begin the activation sequence. t1 is the time for Vcc to rise to acceptable level, declared as Vcc OK (bit VCCOK gets set). This time depends on filter capacitor value and card Icc load.

tto: The time allowed for Vcc to rise to Vcc OK status after setting of the VCCSEL bits. This time is generated by the VCCTMR counter. If Vcc OK is not set, (bit VCCOK) at this time, a deactivation will be initiated. VCCSEL bits are not automatically cleared. The firmware must clear the VCCSEL bits before starting a new activation.

t2: Time from VccTmr timeout and VCC OK to IO reception (high), typically 2-3 CLK cycles if RDYST = 0. If RDYST = 1, t2 starts when VCCOK = 1.

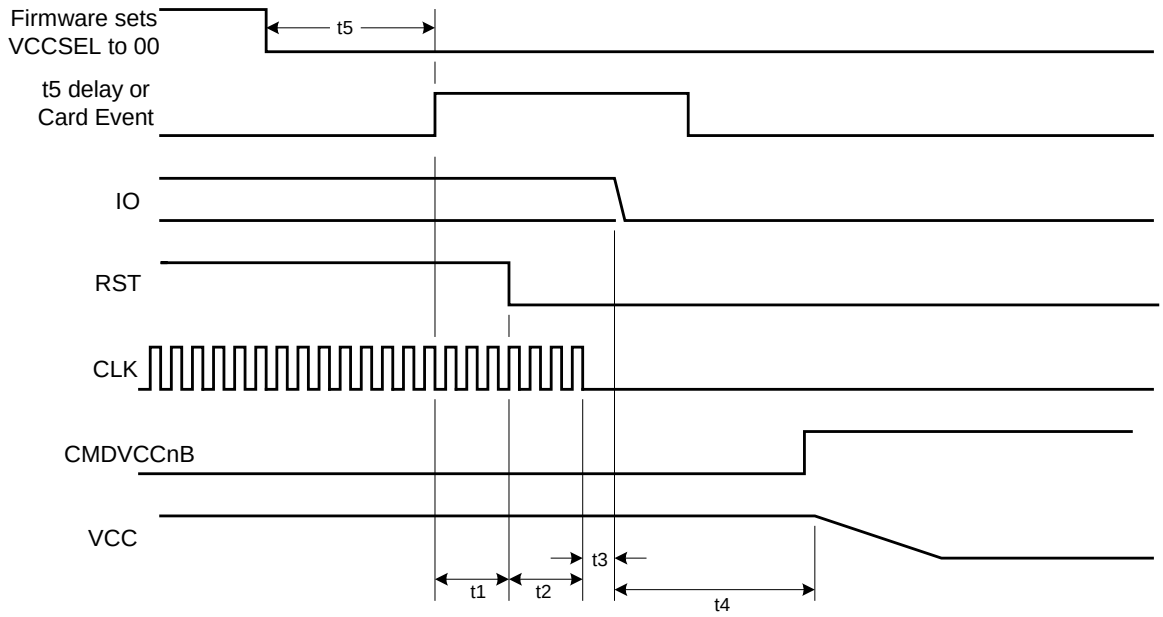
t3: Time from IO = high to CLK start, typically 2-3 CLK cycles.

t4: Time allowed for start of CLK to de-assertion of RST. Programmable by the RLength register.

t5: Time allowed for ATR timeout, set by the STSTO register.

Note: If the RSTCRD bit is set, RST is asserted (low). Upon clearing RSTCRD bit, RST will be de-asserted after t4.

Figure 16: Asynchronous Activation Sequence Timing



t1: Time after either a "card event" occurs or firmware sets the VCCSela and VCCSelb bits to 0 (see t5, VCCOff_tmr) occurs until RST is asserted low.

t2: Time after RST goes low until CLK stops.

t3: Time after CLK stops until IO goes low.

t4: Time after IO goes low until VCC is powered down.

t5: Delayed VCC off time (in ETUs per VCCOff_tmr bits). Only in effect due to firmware deactivation.

Figure 17: Deactivation Sequence

1.7.15.3 Data Reception/Transmission

When a 12Mhz crystal is used, the smart card UART will generate a 3.69Mhz (default) clock to both smart card interfaces. This will allow approximately 9600bps (1/ETU) communication during ATR (ISO 7816 default). As part of the PPS negotiation between the smart card and the reader, the firmware may determine that the smart card parameters F & D may be changed. After this negotiation, the firmware may change the ETU by writing to the SFR FDReg to adjust the ETU and CLK. The firmware may also change the smart card clock frequency by writing to the SFR SCCLK (SCECLK for external interface). Independent clock frequency control is provided to each smart card interface. Clock stop high or Clock stop low is supported in asynchronous mode. Figure 18 shows the ETU and CLK control circuits. The firmware determines when clock stop is supported by the smart card and when it is appropriate to go into that mode (and when to come out of it). The smart card UART is clocked by the same clock that is provided to the selected smart card. The transition between smart card clocks is handled in hardware to eliminate any glitches for the UART during switchover. The external smart card clock is not affected when switching the UART to communicate with the internal smart card.

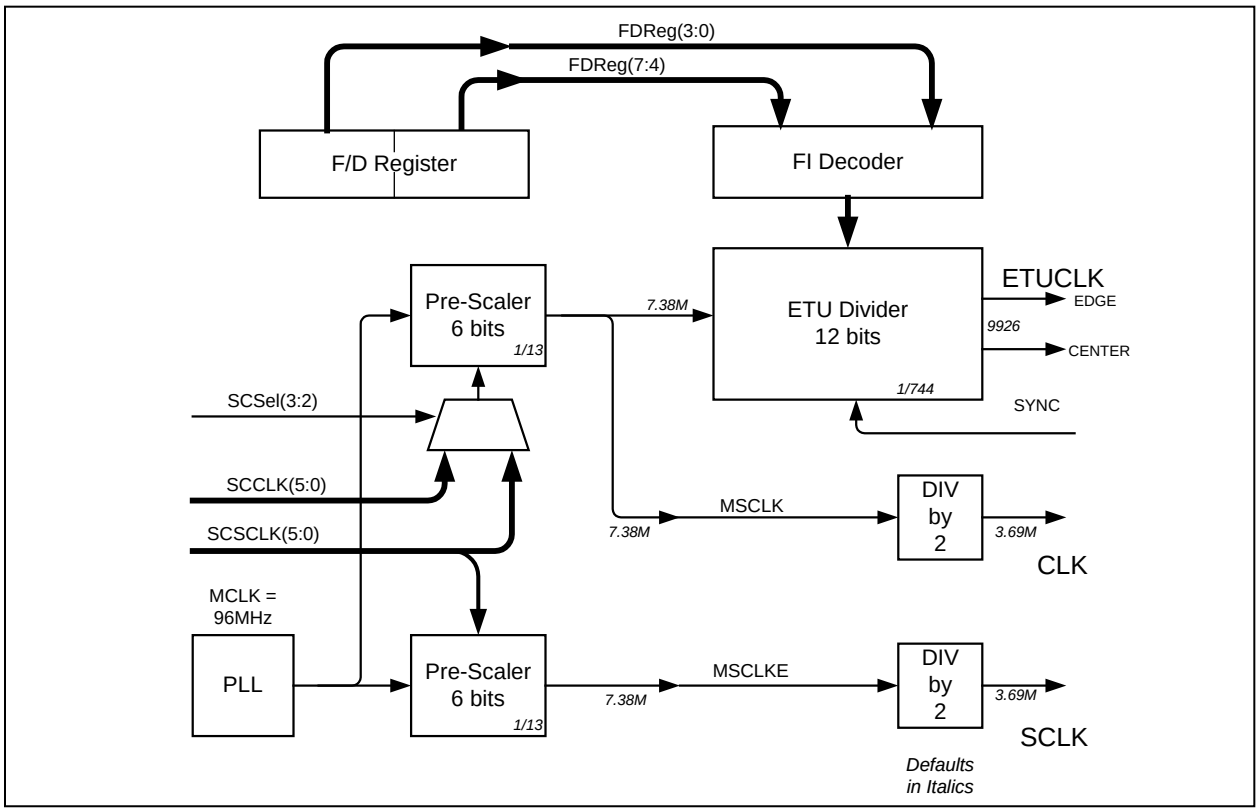


Figure 18: Smart Card CLK and ETU Generation

There are two, two-byte FIFOs that are used to buffer transmit and receive data. During a T=0 processing, if a parity error is detected by the 73S1210F during message reception, an error signal (BREAK) will be generated to the smart card. The byte received will be discarded and the firmware notified of the error. Break generation and receive byte dropping can be disabled under firmware control. During the transmission of a byte, if an error signal (BREAK) is detected, the last byte is retransmitted again and the firmware notified. Retransmission can be disabled by firmware. When a correct byte is received, an interrupt is generated to the firmware, which then reads the byte from the receive FIFO. Receive overruns are detected by the hardware and reported via an interrupt. During transmission of a message, the firmware will write bytes into the transmit FIFO. The hardware will send them to the smart card. When the last byte of a message has been written, the firmware will need to set the LASTTX bit in the STXCtl SFR. This will cause the hardware to insert the CRC/LRC if in a T=1 protocol mode. CRC/LRC generation/checking is only provided during T=1 processing. Firmware will need to instruct the smart function to go into receive mode after this last transmit data byte if it expects a response from the smart card. At the end of the smart card response, the firmware will put the interface back into transmit mode if appropriate.

The hardware can check for the following card-related timeouts:

- Character Waiting Time (CWT)
- Block Waiting Time (BWT)
- Initial Waiting Time (IWT)

The firmware will load the Wait Time with the appropriate value for the operating mode at the appropriate time. Figure 19 shows the guard, block, wait and ATR time definitions. If a timeout occurs, an interrupt will be generated and the firmware can take appropriate recovery steps. Support is provided for adding additional guard times between characters using the Extra Guard Time register (EGT), and between the last byte received by the 73S1210F and the first byte transmitted by the 73S1210F using the Block Guard Time register (BGT). Other than the protocol checks described above, the firmware is responsible for all protocol checking and error recovery.

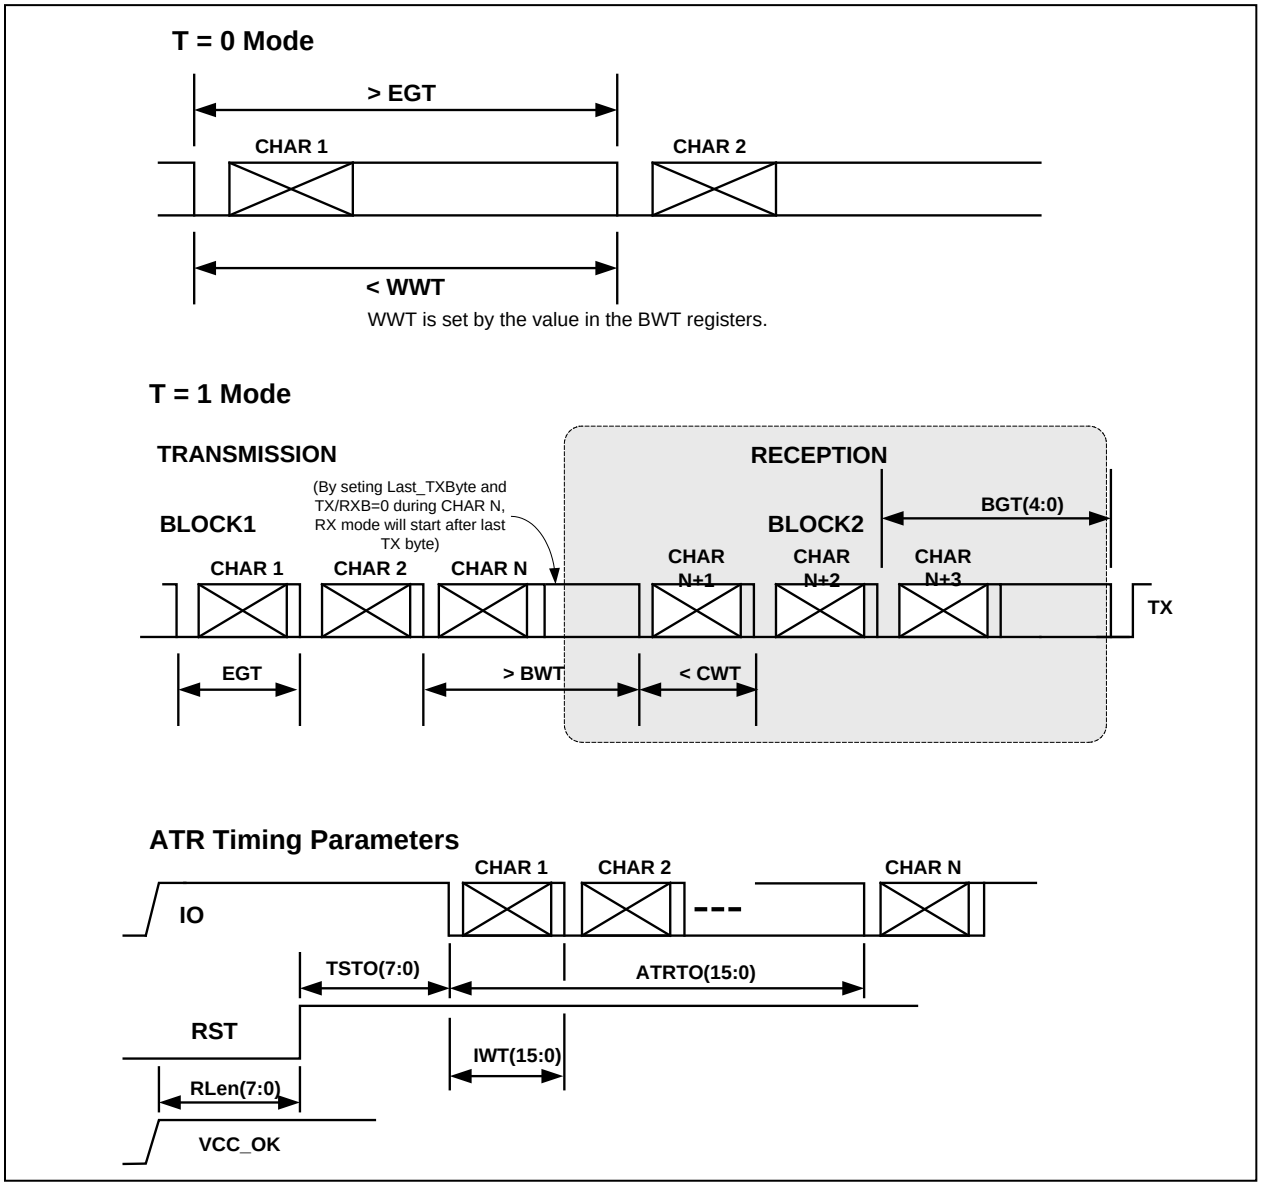

Figure 19: Guard, Block, Wait and ATR Time Definitions

1.7.15.4 Bypass Mode

It is possible to bypass the smart card UART in order for the firmware to support non-T=0/T=1 smart cards. This is called Bypass mode. In this mode the embedded firmware will communicate directly with the selected smart card and drive I/O during transmit and read I/O during receive in order to communicate with the smart card. In this mode, ATR processing is under firmware control. The firmware must sequence the interface signals as required. Firmware must perform TS processing, parity checking, break generation and CRC/LRC calculation (if required).

1.7.15.5 Synchronous Operation Mode

The 73S1210F supports synchronous operation. When sync mode is selected for either interface, the CLK signal is generated by the ETU counter. The values in c, SCCLK, and SCECLK must be set to obtain the desired sync CLK rate. There is only one ETU counter and therefore, in sync mode, the interface must be selected to obtain a smart card clock signal. In sync mode, input data is sampled on the rise of CLK, and output data is changed on the fall of CLK.

Special Notes Regarding Synchronous Mode Operation

When the SCISYN or SCESNC bits (SPrtcol, bit 7, bit 5, respectively) are set, the selected smart card interface operates in synchronous mode and there are changes in the definition and behavior of pertinent register bits and associated circuitry. The following requirements are to be noted:

1. The source for the smart card clock (CLK or SCLK) is the ETU counter. Only the actively selected interface can have a running synchronous clock. In contrast, an unselected interface may have a running clock in the asynchronous mode of operation.

2. The control bits CLKLVL, SCLKLVL, CLKOFF, and SCLKOFF are functional in synchronous mode. When the CLKOFF bit is set, it will not truncate either the logic low or logic high period when the (stop at) level is of opposite polarity. The CLK/SCLK signal will complete a correct logic low or logic high duty cycle before stopping at the selected level. The CLK "start" is a result of the falling edge of the CLKOFF bit. Setting clock to run when it is stopped low will result in a half period of low before going high. Setting clock to run when it is stopped high will result in the clock going low immediately and then running at the selected rate with 50% duty cycle (within the limitations of the ETU divisor value).

3. The Rlen(7:0) is configured to count the falling edges of the ETU clock (CLK or SCLK) after it has been loaded with a value from 1 to 255. A value of 0 disables the counting function and RLen functions such as I/O source selection (I/O signal bypasses the FIFOs and is controlled by the SCCLK/SCECLK SFRs). When the RLen counter reaches the "max" (loaded) value, it sets the WAITTO interrupt (SCInt, bit 7), which is maskable via WTOIEN (SCIE, bit 7). It must be reloaded in order to start the counting/clocking process again. This allows the processor to select the number of CLK cycles and hence, the number of bits to be read or written to/from the card.

4. The FIFO is not clocked by the first CLK (falling) edge resulting from a CLKOFF de-assertion (a clock start event) when the CLK was stopped in the high state and RLen has been loaded but not yet clocked.

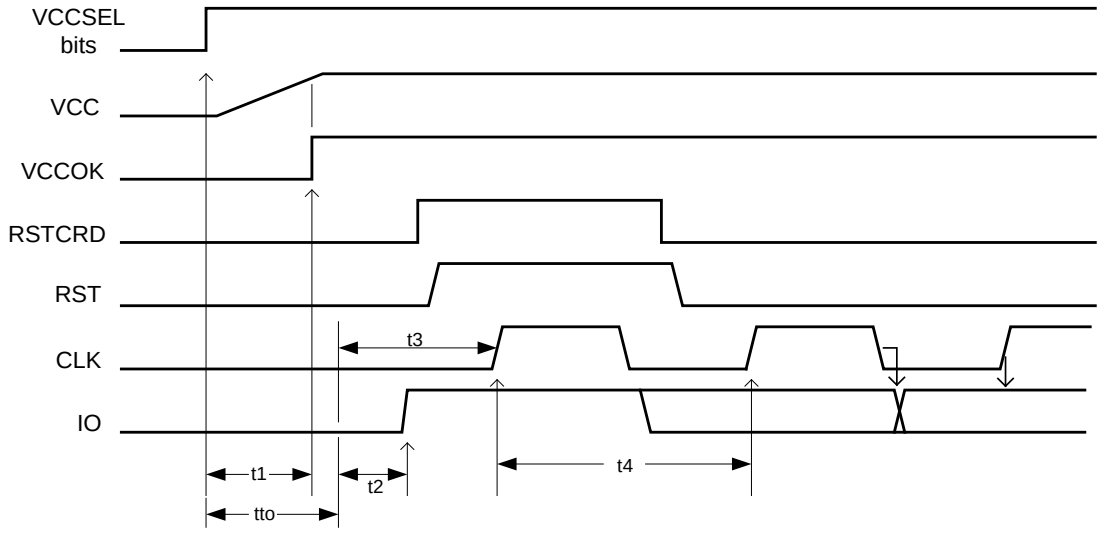
5. The state of the pin IO or SIO is sampled on the rising edge of CLK/SCLK and stored in bit 5 of the SCCtl/SCECtl register.

6. When Rlen = max or 0 and I2CMODE= 1 (STXCtl, b7), the IO or SIO signal is directly controlled by the data and direction bits in the respective SCCtl and SCECtl register. The state of the data in the TX FIFO is bypassed.

7. In the SPrtcol register, bit 6 (MODE9/8B) becomes active. When set, the RXData FIFO will read nine-bit words with the state of the ninth bit being readable in SRXCtl, bit 7 (B9DAT). The RXDAV interrupt will occur when the ninth bit has been clocked in (rising edge of CLK or SCLK).

8. Care must be taken to clear the RX and TX FIFOs at the start of any transaction. The user shall read the RX FIFO until it indicates empty status. Reading the TX FIFO twice will reset the input byte pointer and the next write to the TX FIFO will load the byte to the "first out" position. Note that the bit pointer (serializer/deserializer) is reset to bit 0 on any change of the TX/RXD bit.

Special bits that are only active for sync mode include: SRXCtl, b7 "BIT9DAT", SPrtcol, b6 "MODE9/8B", STXCtl, b7 "I2CMODE", and the definition of SCInt, b7, which was "WAITTO", becomes RLenINT interrupt, and SCIE, b7, which was "WTOIEN", becomes RLenIEN.



t1: The time from setting VCCSEL bits until VCCOK = 1.

tto: The time from setting VCCSEL bits until VCCTMR times out. At t1 (if RDYST = 1) or tto (if RDYST = 0), activation starts. It is suggested to have RDYST = 0 and use the VCCTMR interrupt to let MPU know when sequence is starting.

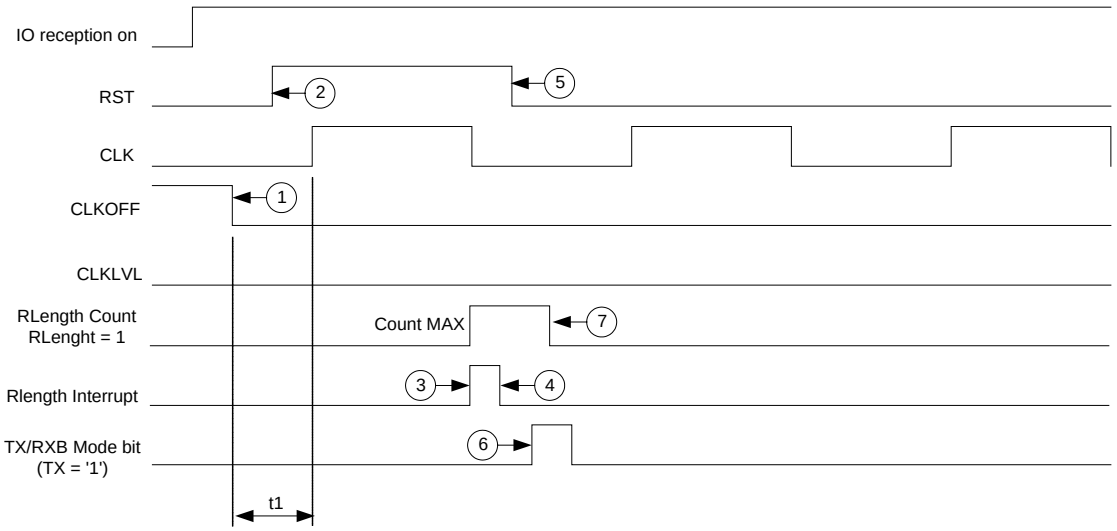
t2: time from start of activation (no external indication) until IO goes into reception mode (= 1). This is approximately 4 SCCLK (or SCECLK) clock cycles.

t3: minimum one half of ETU period.

t4: ETU period.

Note that in Sync mode, IO as input is sampled on the rising edge of CLK. IO changes on the falling edge of CLK, either from the card or from the 73S1210F. The RST signal to the card is directly controlled by the RSTCRD bit (non-inverted) via the MPU and is shown as an example of a possible RST pattern.

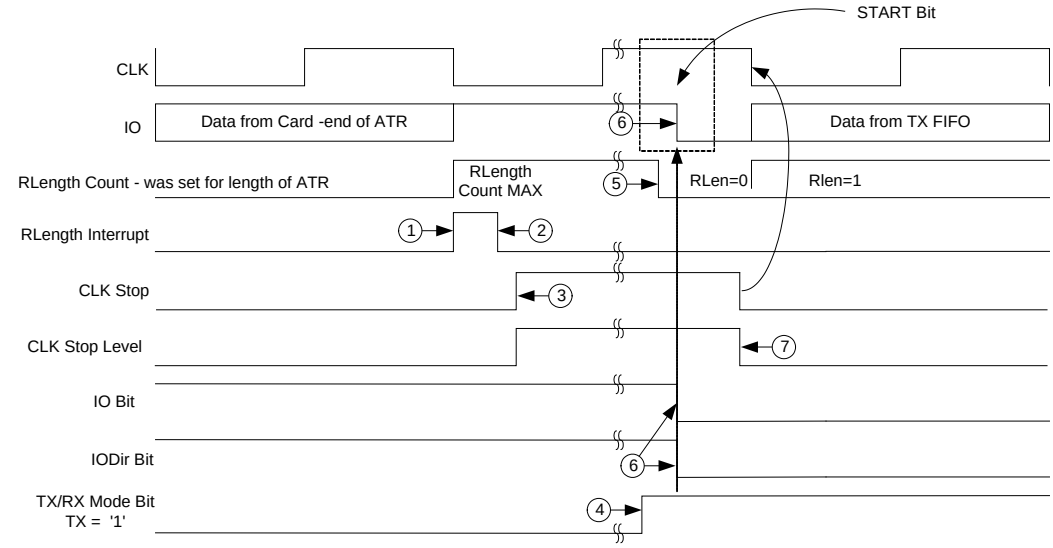
Figure 20: Synchronous Activation



1. Clear CLKOFF after Card is in reception mode.
2. Set RST bit.
3. Interrupt is generated when Rlength counter is MAX.
4. Read and clear Interrupt.
5. Clear RST bit.
6. Toggle TX/RXB to reset bit counter.
7. Reload RLength Counter.

t1. CLK wll start at least 1/2 ETU after CLKOFF is set low when CLKLVL = 0

Figure 21: Example of Sync Mode Operation: Generating/Reading ATR Signals

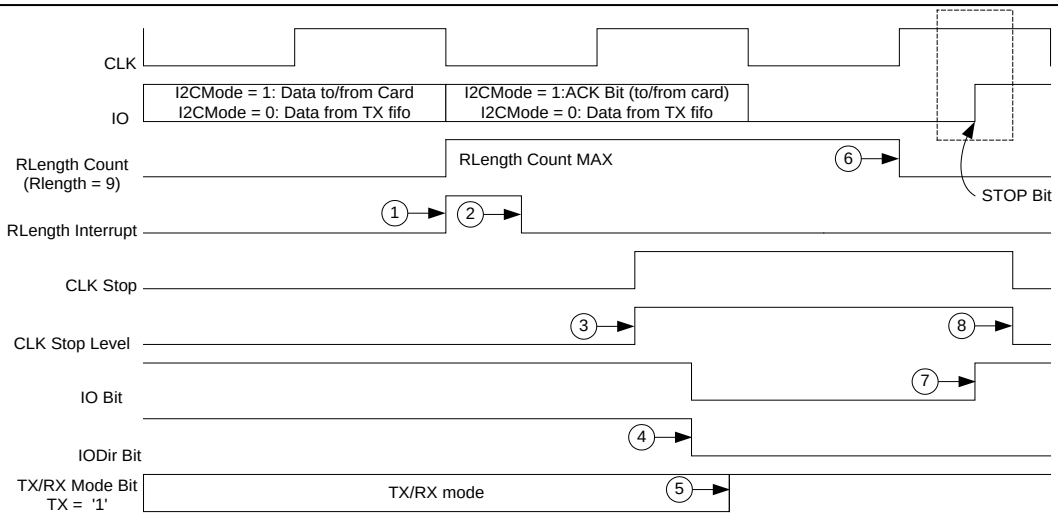


1. Interrupt generated when Rlength counter is MAX.
2. Read and clear Interrupt.
3. Set CLK Stop and CLK Stop level high in Interrupt routine.
4. Set TX/RX Bit to TX mode.
5. Reload Rlength Counter.
6. Set IO Bit low and IODir = Output. Since Rlen=(MAX or 0) and TX/RX =1, IO pin is controlled by IO bit.
7. Clear CLK Stop and CLK Stop level.

Note: Data in TX fifo should not be Empty here.

Synchronous Clock Start/Stop Mode style Start bit procedure. This procedure should be used to generate the start bit insertion in Synchronous mode for Synchronous Clock Start/Stop Mode protocol.

Figure 22: Creation of Synchronous Clock Start/Stop Mode Start Bit in Sync Mode



1. Interrupt generated when Rlength counter is MAX.
2. Read and clear Interrupt.
3. Set CLK Stop and CLK Stop level high.
4. Set IO Bit low and IODir = Output.
5. Set TX/RX Bit to TX mode.
6. Reload Rlength Counter.
7. Set IO Bit High and IODir = Output.
8. Clear CLK Stop and CLK Stop level.

Note: Data in TX fifo should not be Empty here.

Synchronous Clock Start/Stop Mode Stop bit procedure. This procedure should be used to generate the Stop bit in Synchronous Mode. SYCKST is bit 7 of STXCTL register.

Figure 23: Creation of Synchronous Clock Start/Stop Mode Stop Bit in Sync Mode

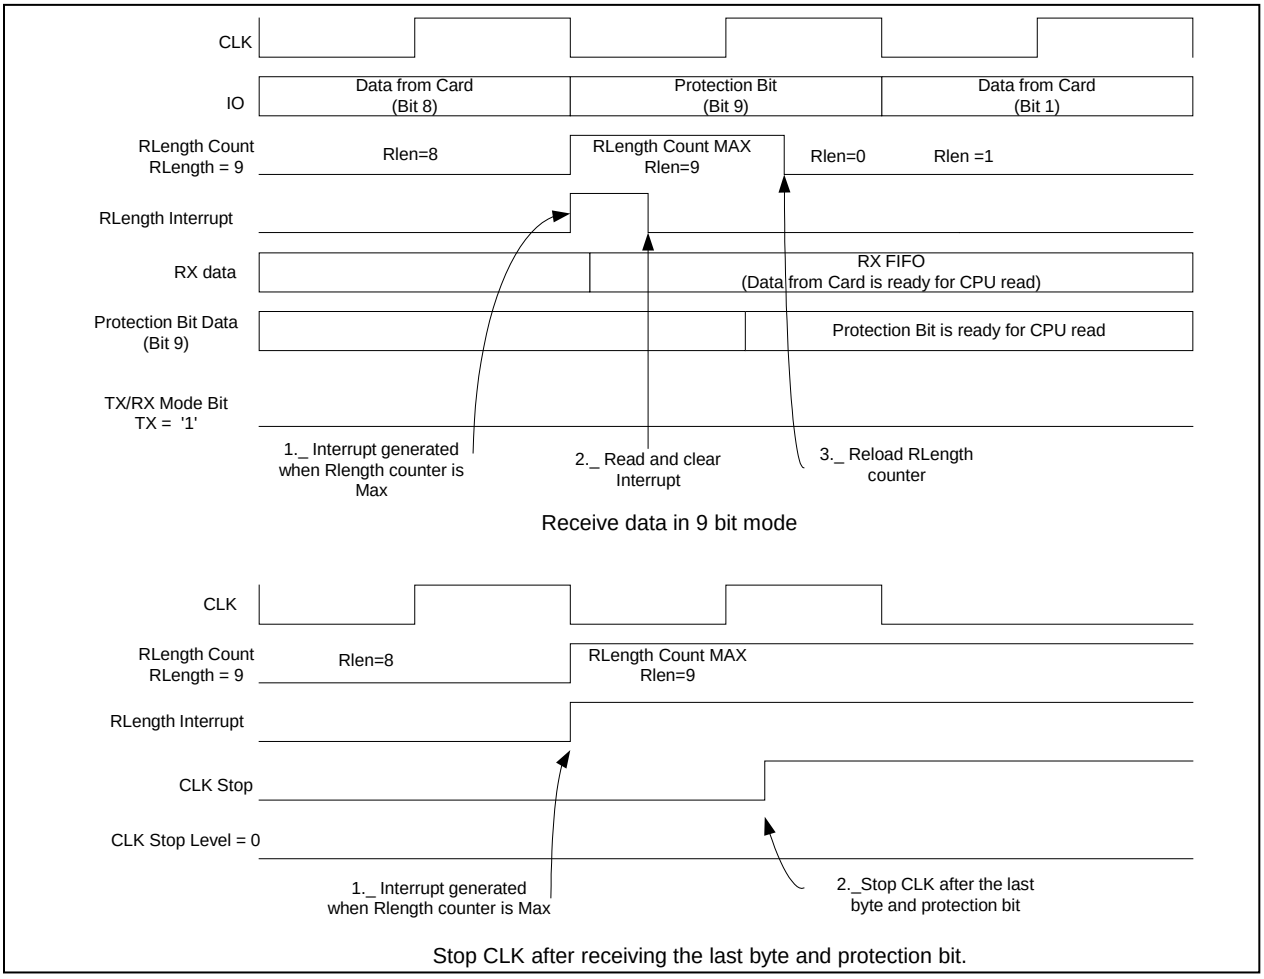


Figure 24: Operation of 9-bit Mode in Sync Mode

Synchronous card operation is broken down into three primary types. These are commonly referred to as 2-wire, 3-wire and I2C synchronous cards. Each card type requires different control and timing and therefore requires different algorithms to access. Teridian has created an application note to provide detailed algorithms for each card type. Refer to the application note titled "*73S12xxF Synchronous Card Design Application Note*".

1.7.15.6 Smart Card SFRs

Smart Card Select Register (SCSel): 0xFE00 ← 0x00

The Smart Card Select register is used to determine which smart card interface is using the ISO UART. The internal Smart Card has integrated 7816-3 compliant sequencer circuitry to drive an external smart card interface. The external smart card interface relies on 73S8010 parts to generate the ISO 7816-3 compatible signals and sequences. Multiple 73S8010 devices can be connected to the external smart card interface.

Table 72: The SCSel Register

MSB							LSB
–	–	–	–	SELSC.1	SELSC.0	BYPASS	–

Bit	Symbol	Function
SCSel.7	–	
SCSel.6	–	
SCSel.5	–	
SCSel.4	–	
SCSel.3	SELSC.1	Select Smart Card Interface - These bits select the interface that is using the IS0 UART. These bits do not activate the interface. Activation is performed by the VccCtl register. 00 = No smart card interface selected. 01 = External Smart Card Interface selected (using SCLK, SIO). 1X = Internal Smart Card Interface selected.
SCSel.2	SELSC.0	
SCSel.1	BYPASS	1 = Enabled, 0 = Disabled. When enabled, ISO UART is bypassed and the I/O line is controlled via the SCCtl and SCECtl registers.
SCSel.0	–	

Smart Card Interrupt Register (SCInt): 0xFE01 ← 0x00

When the smart card interrupt is asserted, the firmware can read this register to determine the actual cause of the interrupt. The bits are cleared when this register is read. Each interrupt can be disabled by the Smart Card Interrupt Enable register. Error processing must be handled by the firmware. This register relates to the interface that is active – see the SCSel register (above).

Table 73: The SCInt Register

MSB LSB

WAITTO	CRDEVT	VCCTMRI	RXDAV	TXEVT	TXSENT	TXERR	RXERR

Bit	Symbol	Function
SCInt.7	WAITTO	Wait Timeout - An ATR or card wait timeout has occurred. In sync mode, this interrupt is asserted when the RLen counter (it advances on falling edges of CLK/ETU) reaches the loaded (max) value. This bit is cleared when the SCInt register is read. When running in Synchronous Clock Stop Mode, this bit becomes RLenINT interrupt (set when the Rlen counter reaches the terminal count).
SCInt.6	CRDEVT	Card Event - A card event is signaled via pin DETCARD either when the Card was inserted or removed (read the CRDCtl register to determine card presence) or there was a fault condition in the interface circuitry. This bit is functional even if the smart card logic clock is disabled and when the PWRDN bit is set. This bit is cleared when the SCInt register is read.
SCInt.5	VCCTMRI	VCC Timer - This bit is set when the VCCTMR times out. This bit is cleared when the SCInt register is read.
SCInt.4	RXDAV	Rx Data Available - Data was received from the smart card because the Rx FIFO is not empty. In bypass mode, this interrupt is generated on a falling edge of the smart card I/O line. After receiving this interrupt in bypass mode, firmware should disable it until the firmware has received the entire byte and is waiting for the next start delimiter. This bit is cleared when there is no RX data available in the RX FIFO.
SCInt.3	TXEVNT	TX Event - Set whenever the TXEMTY or TXFULL bits are set in the SRXCtl SFR. This bit is cleared when the STXCtl register is read.
SCInt.2	TXSENT	TX Sent - Set whenever the ISO UART has successfully transmitted a byte to the smart card. Also set when a CRC/LRC byte is sent in T=1 mode. Will not be set in T=0 when a break is detected at the end of a byte (when break detection is enabled). This bit is cleared when the SCInt register is read.
SCInt.1	TXERR	TX Error - An error was detected during the transmission of data to the smart card as indicated by either BREAKD or TXUNDR bit being set in the STXCtl SFR. Additional information can be found in that register description. This bit is cleared when the STXCtl register is read.
SCInt.0	RXERR	RX Error - An error was detected during the reception of data from the smart card. Additional information can be found in the SRXCtl register. This interrupt will be asserted for RXOVRR, or RX Parity error events. This bit is cleared when the SRXCtl register is read.

Smart Card Interrupt Enable Register (SCIE): 0xFE02 ← 0x00

When set to 1, the respective condition can cause a smart card interrupt. When set to a 0, the respective condition cannot cause an interrupt. When disabled, the respective bit in the Smart Card Interrupt register can still be set, but it will not interrupt the MPU.

Table 74: The SCIE Register

MSB LSB

WTOIEN	CDEVEN	VTMREN	RXDAEN	TXEVEN	TXSNTEN	TXEREN	RXEREN

Bit	Symbol	Function
SCIE.7	WTOIEN	Wait Timeout Interrupt Enable - Enable for ATR or Wait Timeout Interrupt. In sync mode, function is RLIEN (RLen = max.) interrupt enable.
SCIE.6	CDEVEN	Card Event Interrupt Enable.
SCIE.5	VTMREN	VCC Timer Interrupt Enable.
SCIE.4	RXDAEN	Rx Data Available Interrupt Enable.
SCIE.3	TXEVEN	TX Event Interrupt Enable.
SCIE.2	TXSNTEN	TX Sent Interrupt Enable.
SCIE.1	TXEREN	TX Error Interrupt Enable.
SCIE.0	RXEREN	RX Error Interrupt Enable.

Smart Card V_{CC} Control/Status Register (VccCtl): 0xFE03 ← 0x00

This register is used to control the power up and power down of the integrated smart card interface. It is used to determine whether to apply 5V, 3V, or 1.8 to the smart card. Perform the voltage selection with one write operation, setting both VCCSEL.1 and VCCSEL.0 bits simultaneously. The VDDFLT bit (if enabled) will provide an emergency deactivation of the internal smart card slot. See the VDD Fault Detect Function section for more detail.

Table 75: The VccCtl Register

MSB LSB

VCCSEL.1	VCCSEL.0	VDDFLT	RDYST	VCCOK	–	–	SCPWRDN

Bit	Symbol	Function
VccCtl.7	VCCSEL.1	Setting non-zero value for bits 7,6 will begin activation sequence with target Vcc as given below: State VCCSEL.1 VCCSEL.0 VCC 1 0 0 0V 2 0 1 1.8V 3 1 0 3.0V 4 1 1 5V
VccCtl.6	VCCSEL.0	A card event or VCCOK going low will initiate a deactivation sequence. When the deactivation sequence for RST, CLK and I/O is complete, V_{CC} will be turned off. When this type of deactivation occurs, the bits must be reset before initiating another activation.
VccCtl.5	VDDFLT	When there is a VDD Fault event, this bit will be set = 0. This causes VCCSEL.1 and VCCSEL.0 bits to be immediately set = 0 to begin deactivation.
VccCtl.4	RDYST	If this bit is set = 1, the activation sequence will start when bit VCCOK is set = 1. If not set, the deactivation sequence shall start when the VCCTMR times out.
VccCtl.3	VCCOK	(Read only). Indicates that V_{CC} output voltage is stable.
VccCtl.2	–	
VccCtl.1	–	
VccCtl.0	SCPWRDN	This bit controls the power-off mode of the 73S1210F circuit. 1 = power off, 0 = normal operation. When in power down mode, V_{DD} = 0V. V_{DD} can only be turned on by pressing the ON/OFF switch or by application of 5V to V_{BUS}. If V_{BUS} power is available and SCPWRDN bit is set, it has no effect until V_{BUS} is removed and V_{DD} will shut off.

V_{CC} Stable Timer Register (VccTmr): 0xFE04 ← 0x0F

A programmable timer is provided to set the time from activation start (setting the VCCSEL.1 and VCCSEL.0 bits to non-zero) to when VCC_OK is evaluated. VCC_OK must be true at the end of this timers programmed interval (tto in Figure 16) in order for the activation sequence to continue. If VCC_OK is not true and the end of the interval (tto), the Card Event interrupt will be set, and a deactivation sequence shall begin including clearing of the VCCSEL bits.

Table 76: The VccTmr Register

MSB LSB

OFFTMR.3	OFFTMR.2	OFFTMR.1	OFFTMR.0	VCCTMR.3	VCCTMR.2	VCCTMR.1	VCCTMR.0

Bit	Symbol	Function
VccTmr.7	OFFTMR.3	VCC Off Timer - The bits set the delay (in number of ETUs) for deactivation after the VCCSEL.1 and VCC SEL.0 have been set to 0. The time value is a count of the 32768Hz clock and is given by tto = OFFTMR(7:4) * 30.5µs. This delay does not affect emergency deactivations due to VDD Fault or card events. A value of 0000 results in no additional delay.
VccTmr.6	OFFTMR.2	
VccTmr.5	OFFTMR.1	
VccTmr.4	OFFTMR.0	
VccTmr.3	VCCTMR.3	VCC Timer - VCCOK must be true at the time set by the value in these bits in order for the activation sequence to continue. If not, the VCCSEL bits will be cleared. The time value is a count of the 32768Hz clock and is given by tto = VCCTMR(3:0) * 30.5µs. A value of 0000 results in no timeout, not zero time, and activation requires that RDYST is set and RDY goes high.
VccTmr.2	VCCTMR.2	
VccTmr.1	VCCTMR.1	
VccTmr.0	VCCTMR.0	

Card Status/Control Register (CRDCtl): 0xFE05 ← 0x00

This register is used to configure the card detect pin (DETCARD) and monitor card detect status. This register must be written to properly configure Debounce, Detect_Polarity (= 0 or = 1), and the pull-up/down enable before setting CDETEN. The card detect logic is functional even without smart card logic clock. When the PWRDN bit is set = 1, no debounce is provided but card presence is operable.

Table 77: The CRDCtl Register

MSB							LSB
DEBOUN	CDETEN	–	–	DETPOL	PUENB	PDEN	CARDIN

Bit	Symbol	Function
CRDCtl.7	DEBOUN	Debounce - When set = 1, this will enable hardware debounce of the card detect pin. The debounce function shall wait for 64ms of stable card detect assertion before setting the CARDIN bit. This counter/timer uses the keypad clock as a source of 1kHz signal. De-assertion of the CARDIN bit is immediate upon de-assertion of the card detect pin(s).
CRDCtl.6	CDETEN	Card Detect Enable - When set = 1, activates card detection input. Default upon power-on reset is 0.
CRDCtl.5	–	
CRDCtl.4	–	
CRDCtl.3	DETPOL	Detect Polarity - When set = 1, the DETCARD pin shall interpret a logic 1 as card present.
CRDCtl.2	PUENB	Enable pull-up current on DETCARD pin (active low).
CRDCtl.1	PDEN	Enable pull-down current on DETCARD pin.
CRDCtl.0	CARDIN	Card Inserted - (Read only). 1 = card inserted, 0 = card not inserted. A change in the value of this bit is a “card event.” A read of this bit indicates whether smart card is inserted or not inserted in conjunction with the DETPOL setting.

TX Control/Status Register (STXCtl): 0xFE06 ← 0x00

This register is used to control transmission of data to the smart card. Some control and some status bits are in this register.

Table 78: The STXCtl Register

MSB							LSB
I2CMODE	–	TXFULL	TXEMTY	TXUNDR	LASTTX	TX/RXB	BREAKD

Bit	Symbol	Function
STXCtl.7	I2CMODE	I2C Mode - When in sync mode and this bit is set, and when the RLen count value = max or 0, the source of the smart card data for IO pin (or SIO pin) will be connected to the IO bit in SCCtl (or SCECtl) register rather than the TX FIFO. See the description for the Protocol Mode Register for more detail.
STXCtl.6	–	
STXCtl.5	TXFULL	TX FIFO is full. Additional writes may corrupt the contents of the FIFO. This bit it will remain set as long as the TX FIFO is full. Generates a TX_Event interrupt upon going full.
STXCtl.4	TXEMTY	1 = TX FIFO is empty, 0 = TX FIFO is not empty. If there is data in the TX FIFO, the circuit will transmit it to the smart card if in transmit mode. In T=1 mode, if the LASTTX bit is set and the hardware is configured to transmit the CRC/LRC, the TXEMTY will not be set until the CRC/LRC is transmitted. In T=0, if the LASTTX bit is set, TXEMTY will be set after the last word has been successfully transmitted to the smart card. Generates a TXEVNT interrupt upon going empty.
STXCtl.3	TXUNDR	TX Underrrun - (Read only) Asserted when a transmit under-run condition has occurred. An under-run condition is defined as an empty TX FIFO when the last data word has been successfully transmitted to the smart card and the LASTTX bit was not set. No special processing is performed by the hardware if this condition occurs. Cleared when read by firmware. This bit generates a TXERR interrupt.
STXCtl.2	LASTTX	Last TX Byte - Set by firmware (in both T=0 and T=1) when the last byte in the current message has been written into the transmit FIFO. In T=1 mode, the CRC/LRC will be appended to the message. Should be set after the last byte has been written into the transmit FIFO. Should be cleared by firmware before writing first byte of next message into the transmit FIFO. Used in T=0 to determine when to set TXEMTY.
STXCtl.1	TX/RXB	1 = Transmit mode, 0 = Receive mode. Configures the hardware to be receiving from or transmitting to the smart card. Determines which counters should be enabled. This bit should be set to receive mode prior to switching to another interface. Setting and resetting this bit shall initialize the CRC logic. If LASTTX is set, this bit can be reset to RX mode and UART logic will automatically change mode to RX when TX operation is completed (TX_Empty = 1).
STXCtl.0	BREAKD	Break Detected - (Read only) 1 = A break has been detected on the I/O line indicating that the smart card detected a parity error. Cleared when read. This bit generates a TXERR interrupt.

STX Data Register (STXData): 0xFE07 ← 0x00

Table 79: The STXData Register

MSB							LSB
STXDAT.7	STXDAT.6	STXDAT.5	STXDAT.4	STXDAT.3	STXDAT.2	STXDAT.1	STXDAT.0

Bit	Function
STXData.7	Data to be transmitted to smart card. Gets stored in the TX FIFO and then extracted by the hardware and sent to the selected smart card. When the MPU reads this register, the byte pointer is changed to effectively "read out" the data. Thus, two reads will always result in an "empty" FIFO condition. The contents of the FIFO registers are not cleared, but will be overwritten by writes.
STXData.6	
STXData.5	
STXData.4	
STXData.3	
STXData.2	
STXData.1	
STXData.0	

SRX Control/Status Register (SRXCtl): 0xFE08 ← 0x00

This register is used to monitor reception of data from the smart card.

Table 80: The SRXCtl Register

MSB							LSB
BIT9DAT	–	LASTRX	CRCERR	RXFULL	RXEMTY	RXOVRR	PARITYE

Bit	Symbol	Function
SRXCtl.7	BIT9DAT	Bit 9 Data - When in sync mode and with MODE9/8B set, this bit will contain the data on IO (or SIO) pin that was sampled on the ninth CLK (or SCLK) rising edge. This is used to read data in synchronous 9-bit formats.
SRXCtl.6	–	
SRXCtl.5	LASTRX	Last RX Byte - User sets this bit during the reception of the last byte. When byte is received and this bit is set, logic checks CRC to match 0x1D0F (T=1 mode) or LRC to match 00h (T=1 mode), otherwise a CRC or LRC error is asserted.
SRXCtl.4	CRCERR	(Read only) 1 = CRC (or LRC) error has been detected.
SRXCtl.3	RXFULL	(Read only) RX FIFO is full. Status bit to indicate RX FIFO is full.
SRXCtl.2	RXEMTY	(Read only) RX FIFO is empty. This is only a status bit and does not generate an RX interrupt.
SRXCtl.1	RXOVRR	RX Overrun - (Read Only) Asserted when a receive-over-run condition has occurred. An over-run is defined as a byte was received from the smart card when the RX FIFO was full. Invalid data may be in the receive FIFO. Firmware should take appropriate action. Cleared when read. Additional writes to the RX FIFO are discarded when a RXOVRR occurs until the overrun condition is cleared. Will generate an RXERR interrupt.
SRXCtl.0	PARITYE	Parity Error - (Read only) 1 = The logic detected a parity error on incoming data from the smart card. Cleared when read. Will generate an RXERR interrupt.

SRX Data Register (SRXData): 0xFE09 ← 0x00

Table 81: The SRXData Register

MSB LSB

SRXDAT.7	SRXDAT.6	SRXDAT.5	SRXDAT.4	SRXDAT.3	SRXDAT.2	SRXDAT.1	SRXDAT.0

Bit	Function
SRXData.7	(Read only) Data received from the smart card. Data received from the smart card gets stored in a FIFO that is read by the firmware.
SRXData.6	
SRXData.5	
SRXData.4	
SRXData.3	
SRXData.2	
SRXData.1	
SRXData.0	

Smart Card Control Register (SCCtl): 0xFE0A ← 0x21

This register is used to monitor reception of data from the smart card.

Table 82: The SCCtl Register

MSB LSB

RSTCRD	–	IO	IOD	C8	C4	CLKLVL	CLKOFF

Bit	Symbol	Function
SCCtl.7	RSTCRD	1 = Asserts the RST (set RST = 0) to the smart card interface, 0 = De-assert the RST (set RST = 1) to the smart card interface. Can be used to extend RST to the smart card. Refer to RLength register description. This bit is operational in all modes and can be used to extend RST during activation or perform a "Warm Reset" as required. In auto-sequence mode, this bit should be set = 0 to allow the sequencer to de-assert RST per the RLength parameters. In sync mode (see the SPrtcol register) the sense of this bit is non-inverted, if set = 1, RST = 1, if set = 0, RST = 0. Rlen has no effect on Reset in sync mode.
SCCtl.6	–	
SCCtl.5	IO	Smart Card I/O. Read is state of I/O signal (Caution, this signal is not synchronized to the MPU clock). In Bypass mode, write value is state of signal on I/O. In sync mode, this bit will contain the value of I/O pin on the latest rising edge of CLK.
SCCtl.4	IOD	Smart Card I/O Direction control Bypass mode or sync mode. 1 = input (default), 0 = output.
SCCtl.3	C8	Smart Card C8. When C8 is an output, the value written to this bit will appear on the C8 line. The value read when C8 is an output is the value stored in the register. When C8 is an input, the value read is the value on the C8 pin (Caution, this signal is not synchronized to the MPU clock). When C8 is an input, the value written will be stored in the register but not presented to the C8 pin.
SCCtl.2	C4	Smart Card C4. When C4 is an output, the value written to this bit will appear on the C4 line. The value read when C4 is an output is the value stored in the register. When C4 is an input, the value read is the value on the C4 pin (Caution, this signal is not synchronized to the MPU clock). When C4 is an input, the value written will be stored in the register but not presented to the C4 pin.
SCCtl.1	CLKLVL	1 = High, 0 = Low. If CLKOFF is set = 1, the CLK to smart card will be at the logic level indicated by this bit. If in bypass mode, this bit directly controls the state of CLK.
SCCtl.0	CLKOFF	0 = CLK is enabled. 1 = CLK is not enabled. When asserted, the CLK will stop at the level selected by CLKLVL. This bit has no effect if in bypass mode.

External Smart Card Control Register (SCECtl): 0xFE0B ← 0x00

This register is used to directly set and sample signals of External Smart Card interface. There are three modes of asynchronous operation, an "automatic sequence" mode, and bypass mode. Clock stop per the ISO 7816-3 interface is also supported but firmware must handle the protocol for SIO and SCLK for I^2C clock stop and start. Control for Reset (to make RST signal), activation control, voltage select, etc. should be handled via the I^2C interface when using external 73S8010 devices. USR(n) pins shall be used for C4, C8 functions if necessary.

Table 83: The SCECtl Register

MSB LSB

–	–	SIO	SIOD	–	–	SCLKLVL	SCLKOFF

Bit	Symbol	Function
SCECtl.7	–	
SCECtl.6	–	
SCECtl.5	SIO	External Smart Card I/O. Bit when read indicates state of pin SIO for SIOD = 1 (Caution, this signal is not synchronized to the MPU clock), when written, sets the state of pin SIO for SIOD = 0. Ignored if not in bypass or sync modes. In sync mode, this bit will contain the value of IO pin on the latest rising edge of SCLK.
SCECtl.4	SIOD	1 = input, 0 = output. External Smart Card I/O Direction control. Ignored if not in bypass or sync modes.
SCECtl.3	–	
SCECtl.2	–	
SCECtl.1	SCLKLVL	Sets the state of SCLK when disabled by SCLKOFF bit. If in bypass mode, this bit directly controls the state of SCLK.
SCECtl.0	SCLKOFF	0 = SCLK enabled, 1 = SCLK disabled. When disabled, SCLK level is determined by SCLKLVL. This bit has no effect if in bypass mode.

C4/C8 Data Direction Register (SCDIR): 0xFE0C ← 0x00

This register determines the direction of the internal interface C4/C8 lines. After reset, all signals are tri-stated.

Table 84: The SCDIR Register

MSB							LSB
–	–	–	–	C8D	C4D	–	–

Bit	Symbol	Function
SCDIR.7	–	
SCDIR.6	–	
SCDIR.5	–	
SCDIR.4	–	
SCDIR.3	C8D	1 = input, 0 = output. Smart Card C8 direction.
SCDIR.2	C4D	1 = input, 0 = output. Smart Card C4 direction.
SCDIR.1	–	
SCDIR.0	–	

Protocol Mode Register (SPrtcol): 0xFE0D ← 0x03

This register determines the protocol to be use when communicating with the selected smart card. This register should be updated as required when switching between smart card interfaces.

Table 85: The SPrtcol Register

MSB							LSB
SCISYN	MOD9/8B	SCESYN	0	TMODE	CRCEN	CRCMS	RCVATR

Bit	Symbol	Function
SPrtcol.7	SCISYN	Smart Card Internal Synchronous mode - Configures internal smart card interface for synchronous mode. This mode routes the internal interface buffers for RST, IO, C4, C8 to the SCCtl register bits for direct firmware control. CLK is generated by the ETU counter.
SPrtcol.6	MOD9/8B	Synchronous 8/9 bit mode select - For sync mode, in protocols with 9-bit words, set this bit. The first eight bits read go into the RX FIFO and the ninth bit read will be stored in the IO (or SIO) data bit of the SRXCtl register.
SPrtcol.5	SCESYN	Smart Card External Synchronous mode - Configures External Smart Card interface for synchronous mode. This mode routes the external smart card interface buffers for SIO to SCECtl register bits for direct firmware control. SCLK is generated by the ETU counter.
SPrtcol.4	0	Reserved bit, must always be set to 0.
SPrtcol.3	TMODE	Protocol mode select - 0: T=0, 1: T=1. Determines which smart card protocol is to be used during message processing.
SPrtcol.2	CRCEN	CRC Enable – 1 = Enabled, 0 = Disabled. Enables the checking/generation of CRC/LRC while in T=1 mode. Has no effect in T=0 mode. If enabled and a message is being transmitted to the smart card, the CRC/LRC will be inserted into the message stream after the last TX byte is transmitted to the smart card. If enabled, CRC/LRC will be checked on incoming messages and the value made available to the firmware via the CRC LS/MS registers.
SPrtcol.1	CRCMS	CRC Mode Select – 1 = CRC, 0 = LRC. Determines type of checking algorithm to be used.
SPrtcol.0	RCVATR	Receive ATR – 1 = Enable ATR timeout, 0 = Disable ATR timeout. Set by firmware after the smart card has been turned on and the hardware is expecting ATR.

SC Clock Configuration Register (SCCLK): 0xFE0F ← 0x0C

This register controls the internal smart card (CLK) clock generation.

Table 86: The SCCLK Register

MSB							LSB
–	–	ICLKFS.5	ICLKFS.4	ICLKFS.3	ICLKFS.2	ICLKFS.1	ICLKFS.0

Bit	Symbol	Function
SCCLK.7	–	
SCCLK.6	–	
SCCLK.5	ICLKFS.5	Internal Smart Card CLK Frequency Select - Division factor to determine internal smart card CLK frequency. MCLK clock is divided by (register value + 1) to clock the ETU divider, and then by 2 to generate CLK. Default ratio is 13. The programmed value in this register is applied to the divider after this value is written, in such a manner as to produce a glitch-free output, regardless of the selection of active interface. A register value = 0 will default to the same effect as register value = 1.
SCCLK.4	ICLKFS.4	
SCCLK.3	ICLKFS.3	
SCCLK.2	ICLKFS.2	
SCCLK.1	ICLKFS.1	
SCCLK.0	ICLKFS.0	

External SC Clock Configuration Register (SCECLK): 0xFE10 ← 0x0C

This register controls the external smart card (SCLK) clock generation.

Table 87: The SCECLK Register

MSB							LSB
–	–	ECLKFS.5	ECLKFS.4	ECLKFS.3	ECLKFS.2	ECLKFS.1	ECLKFS.0

Bit	Symbol	Function
SCECLK.7	–	
SCECLK.6	–	
SCECLK.5	ECLKFS.5	External Smart Card CLK Frequency Select - Division factor to determine external smart card CLK frequency. MCLK clock is divided by (register value + 1) to clock the ETU divider, and then by 2 to generate SCLK. Default ratio is 13. The programmed value in this register is applied to the divider after this value is written, in such a manner as to produce a glitch-free output, regardless of the selection of active interface. A register value = 0 will default to the same effect as register value = 1.
SCECLK.4	ECLKFS.4	
SCECLK.3	ECLKFS.3	
SCECLK.2	ECLKFS.2	
SCECLK.1	ECLKFS.1	
SCECLK.0	ECLKFS.0	

Parity Control Register (SParCtl): 0xFE11 ← 0x00

This register provides the ability to configure the parity circuitry on the smart card interface. The settings apply to both integrated smart card interfaces.

Table 88: The SParCtl Register

MSB LSB

–	DISPAR	BRKGEN	BRKDET	RETRAN	DISCRX	INSPE	FORCPE

Bit	Symbol	Function
SParCtl.7	–	
SParCtl.6	DISPAR	Disable Parity Check – 1 = disabled, 0 = enabled. If enabled, the UART will check for even parity (the number of 1's including the parity bit is even) on every character. This also applies to the TS during ATR.
SParCtl.5	BRKGEN	Break Generation Disable – 1 = disabled, 0 = enabled. If enabled, and T=0 protocol, the UART will generate a Break to the smart card if a parity error is detected on a receive character. No Break will be generated if parity checking is disabled. This also applies to TS during ATR.
SParCtl.4	BRKDET	Break Detection Disable – 1 = disabled, 0 = enabled. If enabled, and T=0 protocol, the UART will detect the generation of a Break by the smart card.
SParCtl.3	RETRAN	Retransmit Byte – 1 = enabled, 0 = disabled. If enabled and a Break is detected from the smart card (Break Detection must be enabled), the last character will be transmitted again. This bit applies to T=0 protocol.
SParCtl.2	DISCRX	Discard Received Byte – 1 = enabled, 0 = disabled. If enabled and a parity error is detected (Parity checking must be enabled), the last character received will be discarded. This bit applies to T=0 protocol.
SParCtl.1	INSPE	Insert Parity Error – 1 = enabled, 0 = disabled. Used for test purposes. If enabled, the UART will insert a parity error in every character transmitted by generating odd parity instead of even parity for the character.
SParCtl.0	FORCPE	Force Parity Error – 1 = enabled, 0 = disabled. Used for test purposes. If enabled, the UART will generate a parity error on a character received from the smart card.

Byte Control Register (SByteCtl): 0xFE12 ← 0x2C

This register controls the processing of characters and the detection of the TS byte. When receiving, a Break is asserted at 10.5 ETU after the beginning of the start bit. Break from the card is sampled at 11 ETU.

Table 89: The SByteCtl Register

MSB LSB

–	DETTS	DIRTS	BRKDUR.1	BRKDUR.0	–	–	–

Bit	Symbol	Function
SByteCtl.7	–	
SByteCtl.6	DETTS	Detect TS Byte – 1 = Next Byte is TS, 0 = Next byte is not TS. When set, the hardware will treat the next character received as the TS and determine if direct or indirect convention is being used. Direct convention is the default used if firmware does not set this bit prior to transmission of TS by the smart card to the firmware. The hardware will check parity and generate a break as defined by the DISPAR and BRKGEN bits in the parity control register. This bit is cleared by hardware after TS is received. TS is decoded prior to the FIFO and is stored in the receive FIFO.
SByteCtl.5	DIRTS	Direct Mode TS Select – 1 = direct mode, 0 = indirect mode. Set/cleared by hardware when TS is processed indicating either direct/indirect mode of operation. When switching between smart cards, the firmware should write the bit appropriately since this register is not unique to an individual smart card (firmware should keep track of this bit).
SByteCtl.4	BRKDUR.1	Break Duration Select – 00 = 1 ETU, 01 = 1.5 ETU, 10 = 2 ETU, 11 = reserved. Determines the length of a Break signal which is generated when detecting a parity error on a character reception in T=0 mode.
SByteCtl.3	BRKDUR.0	
SByteCtl.2	–	
SByteCtl.1	–	
SByteCtl.0	–	

FD Control Register (FDReg): 0xFE13 ← 0x11

This register uses the transmission factors F and D to set the ETU (baud) rate. The values in this register are mapped to the ISO 7816 conversion factors as described below. The CLK signal for each interface is created by dividing a high-frequency, intermediate signal (MSCLK) by 2. The ETU baud rate is created by dividing MSCLK by 2 times the Fi/Di ratio specified by the codes below. For example, if FI = 0001 and DI = 0001, the ratio of Fi/Di is 372/1. Thus the ETU divider is configured to divide by 2 * 372 = 744. The maximum supported F/D ratio is 4096.

Table 90: The FDReg Register

MSB LSB

FVAL.3	FVAL.2	FVAL.1	FVAL.0	DVAL.3	DVAL.2	DVAL.1	DVAL.0

Table 91: The FDReg Bit Functions

Bit	Symbol	Function
FDReg.7	FVAL.3	Refer to the Table 93 above. This value is converted per the table to set the divide ratio used to generate the baud rate (ETU). Default, also used for ATR, is 0001 (Fi = 372). This value is used by the selected interface.
FDReg.6	FVAL.2	
FDReg.5	FVAL.1	
FDReg.4	FVAL.0	
FDReg.3	DVAL.3	Refer to Table 93 above. This value is used to set the divide ratio used to generate the smart card CLK. Default, also used for ATR, is 0001 (Di = 1).
FDReg.2	DVAL.2	
FDReg.1	DVAL.1	
FDReg.0	DVAL.0	

Table 92: Divider Ratios Provided by the ETU Counter

FI (code)	0000	0001	0010	0011	0100	0101	0110	0111
Fi (ratio)	372	372	558	744	1116	1488	1860	1860⊕

CRC MS Value Registers (CRCMsB): 0xFE14 ← 0xFF, (CRCLsB): 0xFE15 ← 0xFF

Table 94: The CRCMsB Register

MSB							LSB
CRC.15	CRC.14	CRC.13	CRC.12	CRC.11	CRC.10	CRC.9	CRC.8

MSB							LSB
CRC.7	CRC.6	CRC.5	CRC.4	CRC.3	CRC.2	CRC.1	CRC.0

The 16-bit CRC value forms the TX CRC word in TX mode (write value) and the RX CRC in RX mode (read value). The initial value of CRC to be used when generating a CRC to be transmitted at the end of a message (after the last TX byte is sent) when enabled in T=1 mode. Should be reloaded at the beginning of every message to be transmitted. When using CRC, both CRC registers should be initialized to FF. When using LRC, the CRCLsB value register should be loaded to 00. When receiving a message, the firmware should load this with the initial value and then read this register to get the final value at the end of the message. These registers need to be reloaded for each new message to be received. When in LRC mode, bits (7:0) are used and bits (15:8) are undefined. During LRC/CRC checking and generation, this register is updated with the current value and can be read to aid in debugging. This information will be transmitted to the smart card using the timing specified by the Guard Time register. When checking CRC/LRC on an incoming message (CRC/LRC is checked against the data and CRC/LRC), the firmware reads the final value after the message has been received and determines if an error occurred (= 0x1D0F (CRC) no error, else error; = 0 (LRC) no error, else error). When a message is received, the CRC/LRC is stored in the FIFO. The polynomial used to generate and check CRC is $x^{16} + x^{12} + x^5 + 1$. When in indirect convention, the CRC is generated prior to the conversion into indirect convention. When in indirect convention, the CRC is checked after the conversion out of indirect convention. For a given message, the CRC generated (and readable from this register) will be the same whether indirect or direct convention is used to transmit the data to the smart card. The CRCLsB / CRCMsB registers will be updated with CRC/LRC whenever bits are being received or transmitted from/to the smart card (even if CRCEN is not set and in mode T1). They are available to the firmware to use if desired.

Block Guard Time Register (BGT): 0xFE16 ← 0x10

This register contains the Extra Guard Time Value (EGT) most-significant bit. The Extra Guard Time indicates the minimum time between the leading edges of the start bit of consecutive characters. The delay is depends on the T=0/T=1 mode. Used in transmit mode. This register also contains the Block Guard Time (BGT) value. Block Guard Time is the minimum time between the leading edge of the start bit of the last character received and the leading edge of the start bit of the first character transmitted. This should not be set less than the character length. The transmission of the first character will be held off until BGT has elapsed regardless of the TX data and TX/RX control bit timing.

Table 95: The BGT Register

MSB							LSB
EGT.8	–	–	BGT.4	BGT.3	BGT.1	BGT.2	BGT.0

Bit	Symbol	Function
BGT.7	EGT.8	Most-significant bit for 9-bit EGT timer. See the EGT register.
BGT.6	–	
BGT.5	–	
BGT.4	BGT.4	Time in ETUs between the start bit of the last received character to start bit of the first character transmitted to the smart card. Default value is 22.
BGT.3	BGT.3	
BGT.2	BGT.2	
BGT.1	BGT.1	
BGT.0	BGT.0	

Extra Guard Time Register (EGT): 0xFE17 ← 0x0C

This register contains the Extra Guard Time Value (EGT) least-significant byte. The Extra Guard Time indicates the minimum time between the leading edges of the start bit of consecutive characters. The delay depends on the T=0/T=1 mode. Used in transmit mode.

Table 96: The EGT Register

MSB							LSB
EGT.7	EGT.6	EGT.5	EGT.4	EGT.3	EGT.1	EGT.2	EGT.0

Bit	Function
EGT.7	Time in ETUs between start bits of consecutive characters. In T=0 mode, the minimum is 1. In T=0, the leading edge of the next start bit may be delayed if there is a break detected from the smart card. Default value is 12. In T=0 mode, regardless of the value loaded, the minimum value is 12, and for T=1 mode, the minimum value is 11.

EGT.0	

Block Wait Time Registers (BWTB0): 0xFE1B ← 0x00, (BWTB1): 0xFE1A ← 0x00, (BWTB2): 0xFE19 ← 0x00, (BWTB3): 0xFE18 ← 0x00

These registers are used to set the Block Waiting Time(27:0) (BWT). All of these parameters define the maximum time the 73S1210F will have to wait for a character from the smart card. These registers serve a dual purpose. When T=1, these registers are used to set up the block wait time. The block wait time defines the time in ETUs between the beginning of the last character sent to smart card and the start bit of the first character received from smart card. It can be used to detect an unresponsive card and should be loaded by firmware prior to writing the last TX byte. When T=0, these registers are used to set up the work wait time. The work wait time is defined as the time between the leading edge of two consecutive characters being sent to or from the card. If a timeout occurs, an interrupt is generated to the firmware. The firmware can then take appropriate action. A Wait Time Extension (WTX) is supported with the 28-bit BWT.

Table 97: The BWTB0 Register

MSB							LSB

Table 100: The BWTB3 Register

MSB							LSB
–	–	–	–	BWT.27	BWT.26	BWT.25	BWT.24

Character Wait Time Registers (CWTB0): 0xFE1D ← 0x00, (CWTB1): 0xFE1C ← 0x00

These registers are used to hold the Character Wait Time(15:0) (CWT) or Initial Waiting Time(15:0) (IWT) depending on the situation. Both the IWT and the CWT measure the time in ETUs between the leading edge of the start of the current character received from the smart card and the leading edge of the start of the next character received from the smart card. The only difference is the mode in which the card is operating. When T=1 these registers are used to configure the CWT and these registers configure the IWT when the ATR is being received. These registers should be loaded prior to receiving characters from the smart card. Firmware must manage which time is stored in the register. If a timeout occurs, an interrupt is generated to the firmware. The firmware can then take appropriate action.

Table 101: The CWTB0 Register

MSB							LSB

ATR Timeout Registers (ATRLsB): 0xFE20 ← 0x00, (ATRMsB): 0xFE1F ← 0x00

These registers form the ATR timeout (ATRTO [15:0]) parameter. Time in ETU between the leading edge of the first character and leading edge of the last character of the ATR response. Timer is enabled when the RCVATR is set and starts when leading edge of the first start bit is received and disabled when the RCVATR is cleared. An ATR timeout is generated if this time is exceeded.

Table 103: The ATRLsB Register

MSB							LSB

ATRTO.15	ATRTO.14	ATRTO.13	ATRTO.12	ATRTO.11	ATRTO.10	ATRTO.9	ATRTO.8

TS Timeout Register (STSTO): 0xFE21 ← 0x00

The TS timeout is the time in ETU between the de-assertion of smart card reset and the leading edge of the TS character in the ATR (when DETTS is set). The timer is started when smart card reset is de-asserted. An ATR timeout is generated if this time is exceeded (MUTE card).

Table 105: The STSTO Register

MSB							LSB
TST0.7	TST0.6	TST0.5	TST0.4	TST0.3	TST0.1	TST0.2	TST0.0

Reset Time Register (RLength): 0xFE22 ← 0x70

Time in ETUs that the hardware delays the de-assertion of RST. If set to 0 and RSTCRD = 0, the hardware adds no extra delay and the hardware will release RST after VCCOK is asserted during power-up. If set to 1, it will delay the release of RST by the time in this register. When the firmware sets the RSTCRD bit, the hardware will assert reset (RST = 0 on pin). When firmware clears the bit, the hardware will release RST after the delay specified in Rlen. If firmware sets the RSTCRD bit prior to instructing the power to be applied to the smart card, the hardware will not release RST after power-up until RLen after the firmware clears the RSTCRD bit. This provides a means to power up the smart card and hold it in reset until the firmware wants to release the RST to the selected smart card. Works with the selected smart card interface.

Table 106: The RLength Register

MSB							LSB
RLen.7	RLen.6	RLen.5	RLen.4	RLen.3	RLen.1	RLen.2	RLen.0

1.7.16 VDD Fault Detect Function

The 73S1210F contains a circuit to detect a low-voltage condition on the supply voltage V_{DD}. If enabled, it will deactivate the active internal smart card interface when V_{DD} falls below the V_{DD} Fault threshold. The register configures the V_{DD} Fault threshold for the nominal default of 2.3V* or a user selectable threshold. The user's code may load a different value using the FOVRVDDF bit = 1 after the power-up cycle has completed.

VDDFault Control Register (VDDFCtl): 0xFFD4 ← 0x00

Table 108: The VDDFCtl Register

MSB LSB

–	FOVRVDDF	VDDFLTEN	–	STXDAT.3	VDDFTH.2	VDDFTH.1	VDDFTH.0

Bit	Symbol	Function
VDDFCtl.7	–	
VDDFCtl.6	FOVRVDDF	Setting this bit high will allow the VDDFLT(2:0) bits set in this register to control the VDDFault threshold. When this bit is set low, the VDDFault threshold will be set to the factory default setting of 2.3V*.
VDDFCtl.5	VDDFLTEN	Set = 1 will disable VDD Fault operation.
VDDFCtl.4	–	
VDDFCtl.3	–	
VDDFCtl.2	VDDFTH.2	VDD Fault Threshold. Bit Value(2:0) VDDFault Voltage 000 2.3 (nominal default) 001 2.4 010 2.5 011 2.6 100 2.7 101 2.8 110 2.9 111 3.0
VDDFCtl.1	VDDFTH.1	
VDDFCtl.0	VDDFTH.0	

* Note: The V_{DD} Fault factory default can be set to any threshold as defined by bits VDDFTH(2:0). The 73S1210F has the capability to burn fuses at the factory to set the factory default to any of these voltages. Contact Teridian for further details.

2 Typical Application Schematic

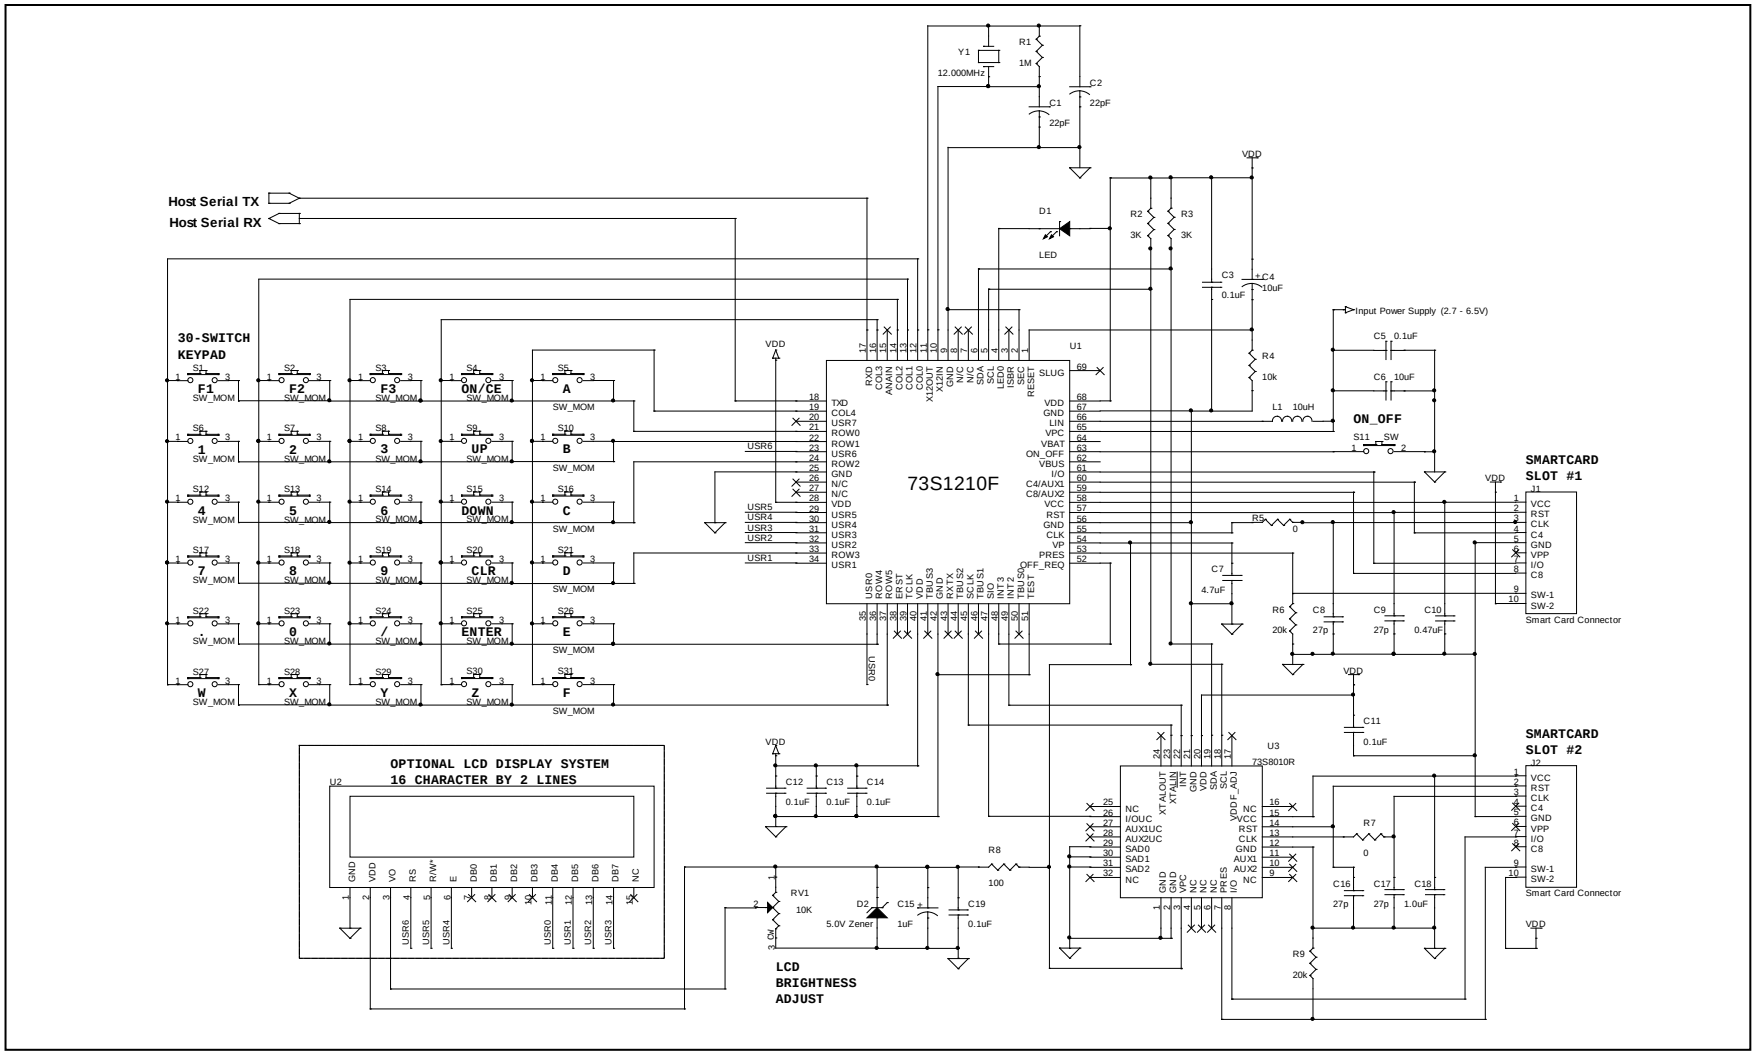

Figure 25: 73S1210F Typical Application Schematic

3 Electrical Specification

3.1 Absolute Maximum Ratings

Operation outside these rating limits may cause permanent damage to the device. The smart card interface pins are protected against short circuits to V_{CC}, ground, and each other.

Parameter	Rating
DC Supply voltage, V_{DD}	-0.5 to 4.0 VDC
Supply Voltage V_{PC}	-0.5 to 6.6 VDC
Supply Voltage V_{BUS}	-0.5 to 6.6 VDC
Supply Voltage V_{BAT}	-0.5 to 6.6 VDC
Storage Temperature	-60 to 150°C
Pin Voltage (except card interface)	-0.3 to (V_{DD}+0.5) VDC
Pin Voltage (card interface)	-0.3 to (V_{CC}+0.5) VDC
ESD tolerance (except card interface)	+/- 2KV
ESD tolerance (card interface)	+/- 7KV
Pin Current	± 200 mA

Note: ESD testing on smart card pins is HBM condition, 3 pulses, each polarity referenced to ground.
Note: Smart Card pins are protected against shorts between any combinations of Smart Card pins.

3.2 Recommended Operating Conditions

Unless otherwise noted all specifications are valid over these temperatures and supply voltage ranges:

Parameter	Rating
Supply Voltage V_{PC}	2.7 to 6.5 VDC
Supply Voltage V_{BUS}	4.4 to 5.5 VDC
Supply Voltage V_{BAT}	4.0 to 6.5 VDC
Ambient Operating Temperature (Ta)	-40°C to +85°C

3.3 Digital IO Characteristics

These requirements pertain to digital I/O pin types with consideration of the specific pin function and configuration. The LED(1:0) pins have pull-ups that may be enabled. The Row pins have 100kΩ pull-ups.

Symbol	Parameter	Conditions	Min.	Typ.	Max.	Unit
Voh	Output level, high	Ioh = -2mA	0.8 * V_{DD}		V_{DD}	V
		OFF_REQ pin - I_{OH} = -1mA	V_{DD} - 0.45			V
Vol	Output level, low	Iol = 2mA	0		0.3	V
		OFF_REQ pin - Iol = 2mA			0.45	V
Vih	Input voltage, high	2.7v < VDD <3.6v	1.8		V_{DD} +0.3	V
Vil	Input voltage, low	2.7v < VDD <3.6v	-0.3		0.6	V
		RESET, ON_OFF,PRES pins	-0.3		0.8	V
Ileak	Leakage current	0 < Vin < VDD All output modes disabled, pull-up/downs disabled	-5		5	µA
Ipu	Pull-up current	If provided and enabled, Vout < 0.1v	-5			µA
Ipd	Pull-down current	If provided and enabled, Vout > VDD – 0.1v			5	µA

Symbol	Parameter	Conditions	Min.	Typ.	Max.	Unit
Iled	LED drive current	Vout = 1.3V, 2.7v < VDD < 3.6v		2 4 10		mA
Iolkrow	Keypad row output low current	0.0v < Voh < 0.1v when pull-up R is enabled		40	100	µA
Iolkcol	Keypad column output high current	0.0v < Voh < 0.1v when col. is pulled low		1.5	3	mA

3.4 Oscillator Interface Requirements

Symbol	Parameter	Condition	Min	Typ.	Max	Unit
High-Frequency Oscillator (Xin) Parameters. Xin Is Used As Input For External Clock For Test Purposes Only. A Resistor Connecting x12in To x12out Is Required, Value = 1mΩ.						
VILX12IN	Input Low Voltage – X12IN		-0.3	1.5	0.3*VDD	V
VIHX12IN	Input High Voltage – X12IN		0.7*VDD	1.6	Vdd+.0.3	V
IILXTAL	Input Current -X12IN	GND < Vin < Vdd	-10		10	µA
Fxtal	Crystal resonant frequency	Fundamental mode	6		12	MHz

		CPU clock @ 3.69MHz		13.5	15.5	mA
		Power down (-40° to 85°C)		8	50	µA
		Power down (25°C)		6	15	µA
I_{DD_OUT}	Supply Current – pin 68 (available to external circuitry)	Circuit ON			20	mA
I_{VBUS}	Supply Current from V_{BUS}	V_{CC} off, $I_{DDINTERNAL}$ < 20µA		0.2	0.4	mA
I_{VBAT} I_{VPC}	Supply Current from V_{BAT} or V_{PC}	Circuit OFF		0.01	1	µA
$VBUS_{ON}$	V_{BUS} detection threshold			3.5		V
$VBUS_{IDIS}$	V_{BUS} discharge current			50		µA
External Capacitor Values						
C_{VPC}	External filter capacitor for V_{PC}		8.0	10.0	12.0	µF
C_{VP}	External filter capacitor for V_P		2.0	4.7	10.0	µF
C_{VDD}*	External filter capacitors for V_{DD}		0.2		1.0	µF
C_{VCC}	External filter capacitor for V_{CC}	C_{VCC} should be ceramic with low ESR (<100MΩ).	0.2	0.47	1.0	µF

*Note: Recommend on 0.1µF for each V_{DD} pin.

3.8 Current Fault Detection Circuits

Symbol	Parameter	Condition	Min	Typ.	Max	Unit
IV_{Pmax}	V_P over current fault				150	mA
I_{DDmax}	VDD over-current limit		40		100	mA
I_{CCF}	Card overcurrent fault		80		150	mA
I_{CCF1P8}	Card overcurrent fault	V_{CC} = 1.8V	60		130	mA

6 Packaging Information

6.1 68-Pin QFN Package Outline

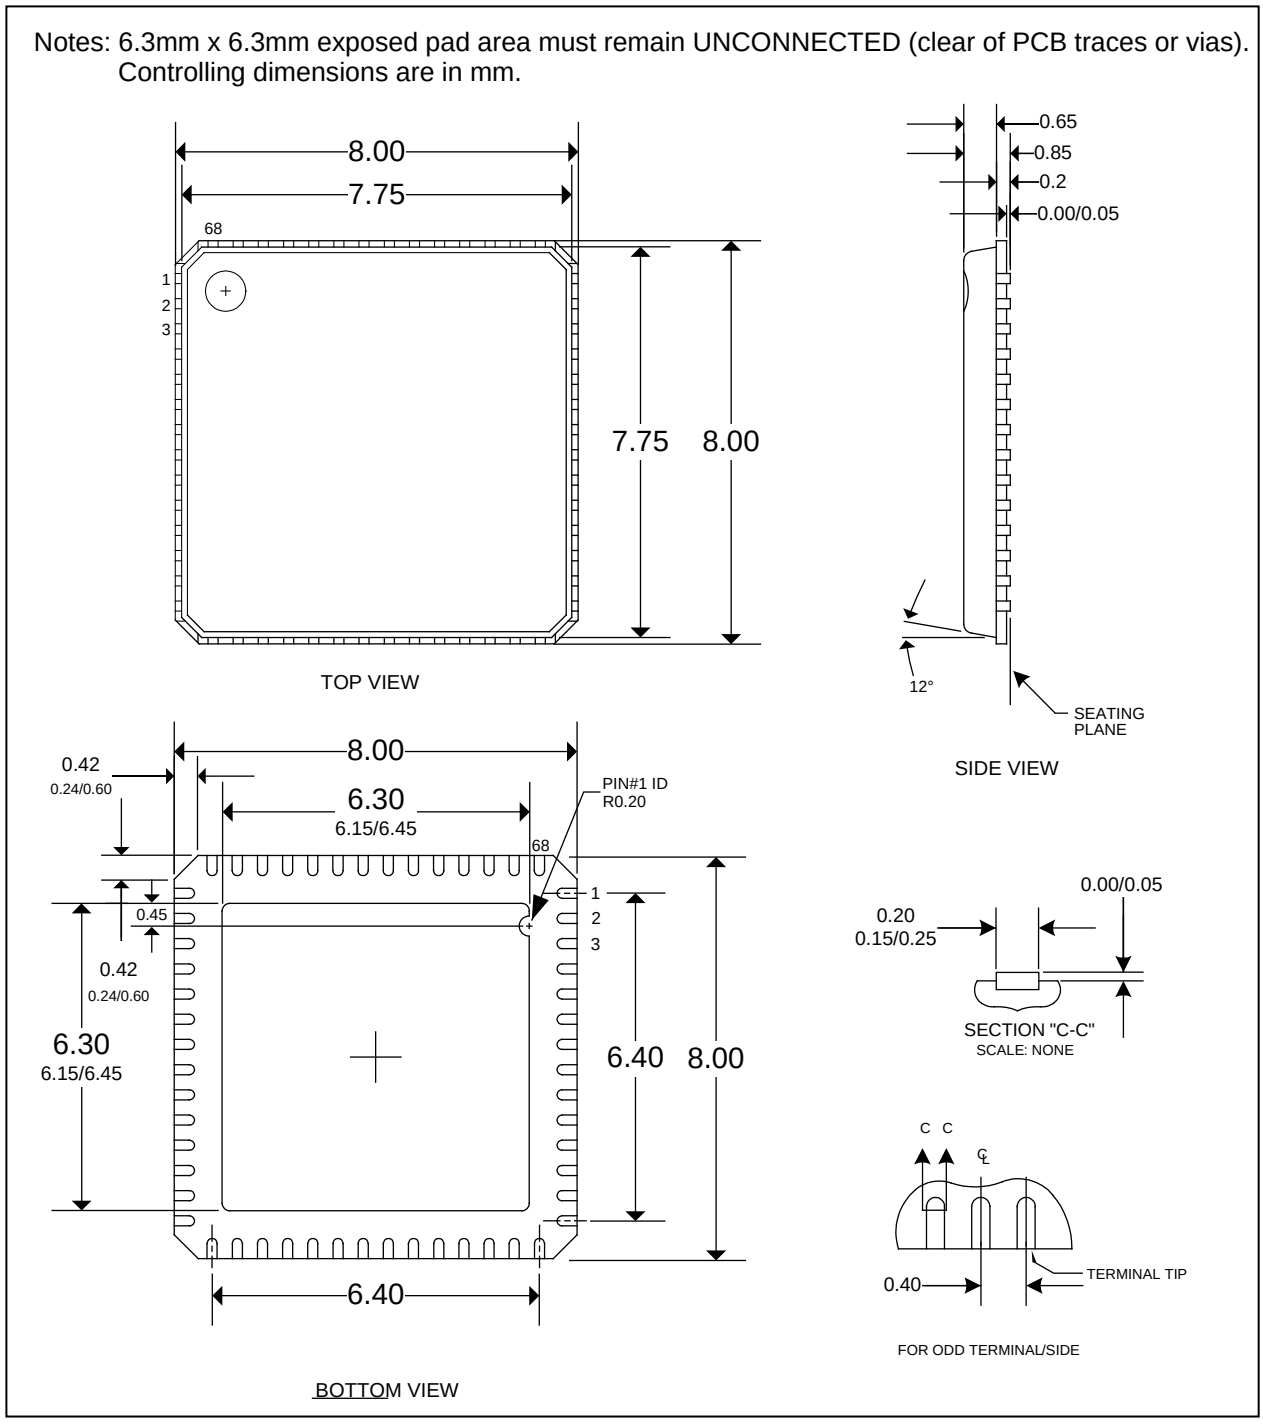

Figure 46: 73S1210F 68 QFN Mechanical Drawing

6.2 44-Pin QFN Package Outline

Notes: 5.1mm x 5.1mm exposed pad area must remain UNCONNECTED (clear of PCB traces or vias). Controlling dimensions are in mm.

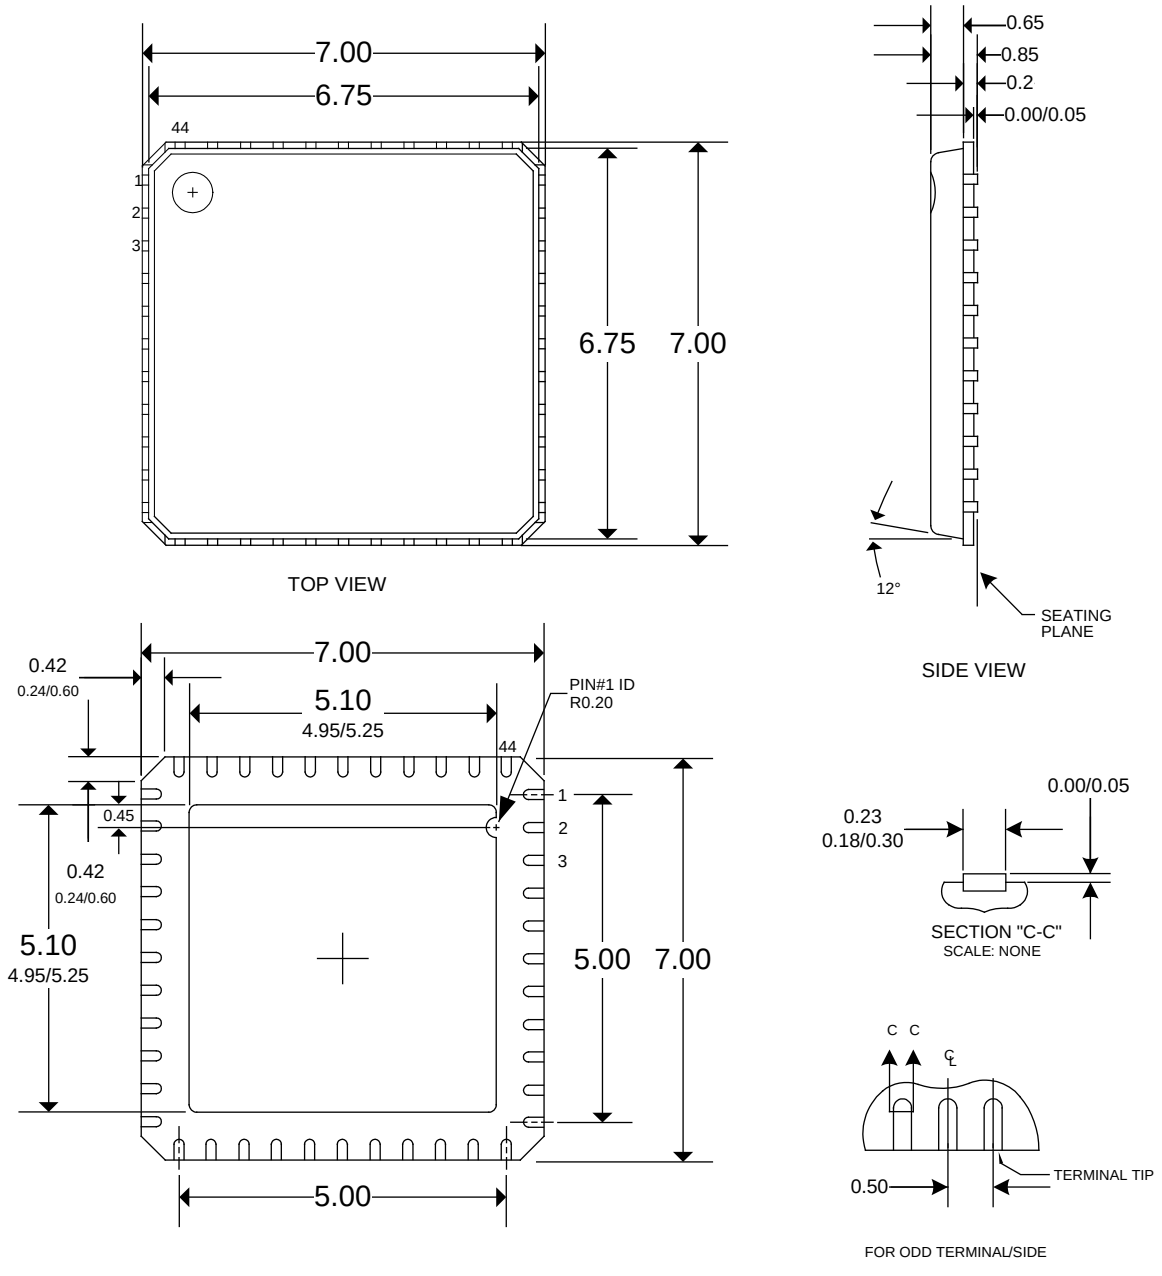

Figure 47: 73S1210F 44 QFN Package Drawing

7 Ordering Information

Table 109 lists the order numbers and packaging marks used to identify 73S1210F products.

Table 109: Order Numbers and Packaging Marks

Part Description	Order Number	Packaging Mark
73S1210F 68-Pin QFN, Lead Free 73S1210F 68-Pin QFN, Lead Free with Programming	73S1210F-68IM/F 73S1210F-68IM/F/P	73S1210F68IM 73S1210F68IM
73S1210F 68-Pin QFN, Lead Free, Tape and Reel 73S1210F 68-Pin QFN, Lead Free, Tape and Reel with Programming	73S1210F-68IMR/F 73S1210F-68IMR/F/P	73S1210F68IM 73S1210F68IM
73S1210F 44-Pin QFN, Lead Free 73S1210F 44-Pin QFN, Lead Free with Programming	73S1210F-44IM/F 73S1210F-44IM/F/P	73S1210F44IM 73S1210F44IM
73S1210F 44-Pin QFN, Lead Free, Tape and Reel 73S1210F 44-Pin QFN, Lead Free, Tape and Reel with Programming	73S1210F-44IMR/F 73S1210F-44IMR/F/P	73S1210F44IM 73S1210F44IM

Revision History

Revision	Date	Description
1.0	5/10/2007	First publication.
1.1	11/6/2007	In Table 1, added Equivalent Circuit references. In Section 1.4, updated program security description to remove pre-boot and 32-cycle references. In Section 1.7.1, changed "Mcount is configured in the MCLKCtl register must be bound between a value of 1 to 7. The possible crystal or external clock are shown in Table 12." to "Mcount is configured in the MCLKCtl register must be bound between a value of 1 to 7. The possible crystal or external clock frequencies for getting MCLK = 96MHz are shown in Table 11." In the BRCON description, changed "If BSEL = 1, the baud rate is derived using timer 1." to "If BSEL = 0, the baud rate is derived using timer 1." In Section 1.7.14, removed the following from the emulator port description: "The signals of the emulator port have weak pull-ups. Adding resistor footprints for signals E_RST, E_TCLK and E_RXTX on the PCB is recommended. If necessary, adding 10KΩ pull-up resistors on E_TCLK and E_RXTX and a 3KΩ on E_RST will help the emulator operate normally if a problem arises." In Ordering Information, removed the leaded part numbers.
1.2	12/15/2008	In Table 1, added the "Pin (44 QFN)" column. In Table 1, added more description to the SCL, SDA, PRES, VCC, VPC, SEC, TEST and VDD pins. In Section 1.3.2, changed "FLSH_ERASE" to "ERASE" and "FLSH_PGADR" to "PGADDR". Added "The PGADDR register denotes the page address for page erase. The page size is 512 (200h) bytes and there are 128 pages within the flash memory. The PGADDR denotes the upper seven bits of the flash memory address such that bit 7:1 of the PGADDR corresponds to bit 15:9 of the flash memory address. Bit 0 of the PGADDR is not used and is ignored." In the description of the PGADDR register, added "Note: the page address is shifted left by one bit (see detailed description above)." In Table 5, changed "FLSHCRL" to "FLSHCTL". In Table 5, removed the PREBOOT bit description. In Table 5, moved the TRIMPCtl bit description to FUSECtl and moved the FUSECtl bit description to TRIMPCtl. In Table 6, changed "PGADR" to "PGADDR". In Table 7, added PGADDR. In Table 8, changed the reset value for RTCCtl from "0x81" to "0x00". Added the RTCTrim0 and ACOMP registers. Deleted the OMP, VRCtl, LEDCal and LOCKCtl registers. In Table 7, removed the Mcount 7 row. In Table 50 through Table 53, changed the names of registers USRIntCtl0 through USRIntCtl3 to USRIntCtl1 through USRIntCtl4. In TCON, corrected the descriptions for TCON.2 and TCON.0. In Section 1.7.9, added a note about USR pins defaulting as inputs after reset. Changed the register address for ATRMsB from FE21 to FE1F.

		In Section 1.7.15.5, deleted "The ETU clock is held in reset condition until the activation sequence begins (either by VCCOK=1 or VCCTMR timeout) and will go high ½ the ETU period thereafter." In Section 1.7.15.5, added "Synchronous card operation is broken down into three primary types. These are commonly referred to as 2-wire, 3-wire and I2C synchronous cards. Each card type requires different control and timing and therefore requires different algorithms to access. Teridian has created an application note to provide detailed algorithms for each card type. Refer to the application note titled *73S12xxF Synchronous Card Design Application Note*." In Table 78 and Table 107, changed the SYCKST bit to I2CMODE. In Figure 25, replaced the schematic with a new schematic. In Section 3.4, changed the Fxtal Min from 4 to 6. Added 44-pin QFN package. Added Section 8, Related Documentation. Added Section 9, Contact Information. Formatted the document per new standard. Added section numbering.
1.3	1/22/2009	Changed the value for the I_{DD_IN} Power Down (25°C) parameter from 13 µA to 15 µA.
1.4	5/12/2009	In Table 1, corrected the 44 QFN GND pin from 37 to 26. Added the "with Programming" ordering numbers to Table 109.
