

**THE DATASHEET OF  
AP1701AWG-7**

**Features**

- Precision Monitoring of +2.5V, +3V, +3.3V, and +5V Power-Supply Voltages
- Fully Specified Over Temperature
- Available in three Output Configurations
- Push-Pull **RESET** Low Output (AP1701/3)
- Push-Pull **RESET** High Output (AP1702/4)
- 200ms Min. Power-On Reset Pulse Width
- 20µA Supply Current (Typ.)
- Guaranteed Reset Valid to  $V_{CC} = +1V$
- Power Supply Transient Immunity
- No External Components
- Green Packages: SC59-3L and SOT23
- Lead Free Finish / RoHS Compliant (Note 1)

**General Description**

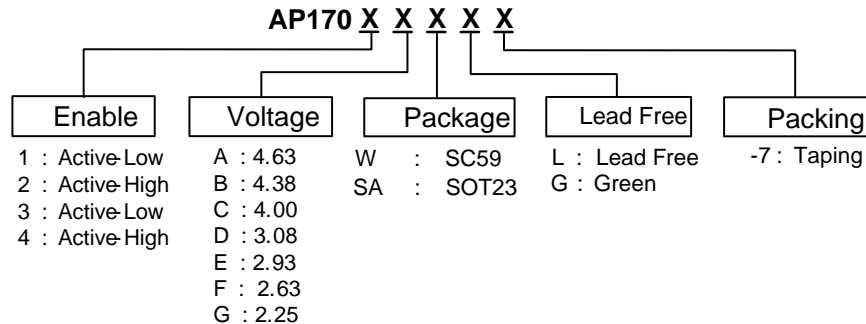

The AP1701/2/3/4 are used for microprocessor ( $\mu P$ ) supervisory circuits to monitor the power supplies in  $\mu P$  and digital systems. They provide excellent circuit reliability and low cost by eliminating external components and adjustments when used with +5V, +3.3V, +3.0V powered circuits.

These circuits perform a single function: they assert a reset signal whenever the  $V_{CC}$  supply voltage declines below a preset threshold, keeping it asserted for at least 240ms after  $V_{CC}$  has risen above the reset threshold. Reset thresholds suitable for operation with a variety of supply voltages are available. The AP1701/2/3/4 have push pull outputs. The AP1701/3 have an active low **RESET** output, while the AP1702/4 has an active high **RESET** output. The reset comparator is designed to ignore fast transients on  $V_{CC}$ , and the outputs are guaranteed to be in the correct logic state for  $V_{CC}$  down to 1V. Low supply current makes the AP1701/2/3/4 ideal for use in portable equipment. The AP1701/2/3/4 is available in a 3-pin SC59 package.

**Applications**

- Computers
- Controllers
- Intelligent Instruments
- Critical  $\mu P$  and  $\mu C$  Power Monitoring
- Portable/Battery Powered Equipment
- Automotive

**Ordering Information**

Notes: 1. RoHS revision 13.2.2003. Glass and High Temperature Solder Exemptions Applied, see *EU Directive Annex Notes 5 and 7*.

Device	Package Code	Packaging (Note 2)	7" Tape and Reel	
			Quantity	Part Number Suffix
AP170XXW	W	SC59	3000/Tape & Reel	-7

	Reset Threshold Tempco			30		ppm/ °C
$T_S$	Set-up Time	$V_{CC} = 0$ to $(V_{TH} - 100\text{mV})$	100			$\mu\text{s}$
$T_{DELAY}$	Reset Active Timeout Period	$T_A = 0^\circ\text{C}$ to $+70^\circ\text{C}$	100	240	600	ms
$V_{OL}$	$\overline{RESET}$ Output Voltage Low	$V_{CC} = V_{TH} \text{ min}, I_{SINK} = 1.2\text{mA}, \text{AP1701/3}$			0.3	V
		$V_{CC} = V_{TH} \text{ min}, I_{SINK} = 3.2\text{mA}$			0.4	
		$V_{CC} > 1.0\text{V}, I_{SINK} = 50\mu\text{A}$			0.3	
$V_{OH}$	$\overline{RESET}$ Output Voltage-High	$V_{CC} > V_{TH} \text{ max}, I_{SOURCE} = 500\mu\text{A}, \text{AP1701/3}$	$0.8V_{CC}$			V
		$V_{CC} > V_{TH} \text{ max}, I_{SOURCE} = 800\mu\text{A}$	$V_{CC} - 1.5$			
$V_{OL}$	RESET Output Voltage-Low	$V_{CC} = V_{TH} \text{ max}, I_{SINK} = 1.2\text{mA}, \text{AP1702/4}$			0.3	V
		$V_{CC} = V_{TH} \text{ max}, I_{SINK} = 3.2\text{mA}$			0.4	
$V_{OH}$	RESET Output Voltage-High	$1.8\text{V} < V_{CC} < V_{TH} \text{ min}, I_{SOURCE} = 150\mu\text{A}, \text{AP1702/4}$	$0.8 V_{CC}$			V

## Typical Application Circuit

## Function Description

A microprocessor's ( $\mu P$ 's) reset input starts the  $\mu P$  in a known state. The AP1701/2/3/4 assert reset to prevent code-execution errors during power-up, power-down, or brownout conditions. They assert a reset signal whenever the  $V_{CC}$  supply voltage declines below a preset threshold, keeping it asserted for at least 240ms after  $V_{CC}$  has risen above the reset threshold. The AP1701/2/3/4 have a push-pull output stage.

### Applications Information

#### Negative-Going $V_{CC}$ Transients

In addition to issuing a reset to the  $\mu P$  during power-up, power-down, and brownout conditions, the AP1701/2/3/4 are relatively immune to short-duration negative-going  $V_{CC}$  transients (glitches).

The AP1701/2/3/4 do not generate a reset pulse. The graph was generated using a negative going pulse applied to  $V_{CC}$ , starting 0.5V above the actual reset threshold and ending below it by the magnitude indicated (reset comparator overdrive). The graph indicates the maximum pulse width a negative going  $V_{CC}$  transient can have without causing a reset pulse. As the magnitude of the transient increases (goes farther below the reset threshold), the maximum allowable pulse width decreases. Typically, a  $V_{CC}$  transient that goes 100mV below the reset threshold and lasts 100 $\mu s$  or less will not cause a reset pulse. A 0.1 $\mu F$  bypass capacitor mounted as close as possible to the  $V_{CC}$  pin provides additional transient immunity.

#### Ensuring a Valid Reset Output Down to $V_{CC} = 0$

$\overline{RESET}$  is guaranteed to be a logic low for  $V_{CC} > 1V$ . Once  $V_{CC}$  exceeds the reset threshold, an internal timer keeps  $\overline{RESET}$  low for the reset timeout period; after this interval,  $\overline{RESET}$  goes high. If a brownout condition occurs ( $V_{CC}$  dips  $\overline{RESET}$

below the reset threshold),  $\overline{RESET}$  goes low. Any time  $V_{CC}$  goes below the reset threshold, the internal timer resets to zero, and  $\overline{RESET}$  goes low. The internal timer starts after  $V_{CC}$  returns above the reset threshold, and  $\overline{RESET}$  remains low for the reset timeout period.

When  $V_{CC}$  falls below 1V, the AP1701/3  $\overline{RESET}$  output no longer sinks current—it becomes an open circuit. Therefore, high-impedance CMOS logic inputs connected to  $\overline{RESET}$  can drift to undetermined voltages. This presents no problem in most applications since most  $\mu P$  and other circuitry is inoperative with  $V_{CC}$  below 1V. However, in applications where  $\overline{RESET}$  must be valid down to 0V, adding a pull down resistor to  $\overline{RESET}$  causes any stray leakage currents to flow to ground, holding  $\overline{RESET}$  low.  $R1$ 's value is not critical; 100k are large enough not to load  $\overline{RESET}$  and small enough to pull  $\overline{RESET}$  to ground. For the AP1702/4 if  $\overline{RESET}$  is required to remain valid for  $V_{CC} < 1V$ .

#### Benefits of Highly Accurate Reset Threshold

Most  $\mu P$  supervisor ICs has reset threshold voltages between 5% and 10% below the value of nominal supply voltages. This ensures a reset will not occur within 5% of the nominal supply, but will occur when the supply is 10% below nominal. When using ICs rated at only the nominal supply  $\pm 5\%$ , this leaves a zone of uncertainty where the supply is between 5% and 10% low, and where the reset may or may not be asserted.
