Single/Dual/Quad, Low-Power, Single-Supply, Rail-to-Rail I/O Op Amps with Shutdown

MAX4330-MAX4334

General Description

The MAX4330-MAX4334 single/dual/quad op amps combine a wide 3MHz bandwidth, low-power operation, and excellent DC accuracy with Rail-to-Rail® inputs and outputs. These devices require only 245µA per amplifier, and operate from either a single +2.3V to +6.5V supply or dual ±1.15V to ±3.25V supplies. The input common-mode voltage range extends 250mV beyond V_{EE} and V_{CC}, and the outputs swing rail-to-rail. The MAX4331/MAX4333 feature a shutdown mode in which the output goes high impedance and the supply current decreases to 9µA per amplifier.

Low-power operation combined with rail-to-rail input common-mode range and output swing makes these amplifiers ideal for portable/battery-powered equipment and other low-voltage, single-supply applications. Although the minimum operating voltage is specified at 2.3V, these devices typically operate down to 2.0V. Low offset voltage and high speed make these amplifiers excellent choices for signal-conditioning stages in precision, low-voltage data-acquisition systems. The MAX4330 is available in the space-saving 5-pin SOT23 package, and the MAX4331/MAX4333 are offered in a µMAX package.

Features

- ◆ 3MHz Gain-Bandwidth Product
- ◆ 245µA Quiescent Current per Amplifier
- ◆ Available in Space-Saving SOT23-5 Package (MAX4330)
- ◆ +2.3V to +6.5V Single-Supply Operation
- ◆ Rail-to-Rail Input Common-Mode Voltage Range
- ◆ Rail-to-Rail Output Voltage Swing
- ◆ 250µV Offset Voltage
- ◆ Low-Power, 9µA (per amp) Shutdown Mode (MAX4331/MAX4333)
- ◆ No Phase Reversal for Overdriven Inputs
- ◆ Capable of Driving 2kΩ Loads
- ◆ Unity-Gain Stable

Detailed Description

Rail-to-Rail Input Stage

The MAX4330-MAX4334 have rail-to-rail input and output stages that are specifically designed for low-voltage, single-supply operation. The input stage consists of separate NPN and PNP differential stages, which operate together to provide a common-mode range extending to 0.25V beyond both supply rails. The crossover region, which occurs halfway between V_{CC} and V_{EE} , is extended to minimize degradation in CMRR caused by mismatched input pairs. The input offset voltage is typically 250 μ V. Low offset voltage, high bandwidth, rail-to-rail common-mode input range, and rail-to-rail outputs make this family of op amps an excellent choice for precision, low-voltage data-acquisition systems.

Since the input stage consists of NPN and PNP pairs, the input bias current changes polarity as the input voltage passes through the crossover region. Match the effective impedance seen by each input to reduce the offset error due to input bias currents flowing through external source impedances (Figures 1a and 1b). The combination of high source impedance with input capacitance (amplifier input capacitance plus stray capacitance) creates a parasitic pole that produces an underdamped signal response. Reducing input capacitance or placing a small capacitor across the feedback resistor improves response.

The MAX4330-MAX4334's inputs are protected from large differential input voltages by internal 1k Ω series resistors and back-to-back triple diode stacks across the inputs (Figure 2). For differential input voltages (much less than 1.8V), input resistance is typically 2.3M Ω . For differential input voltages greater than 1.8V, input resistance is around 2k Ω , and the input bias current can be approximated by the following equation:

$$I_{BIAS} = (V_{DIFF} - 1.8V) / 2k\Omega$$

In the region where the differential input voltage approaches 1.8V, input resistance decreases exponentially from 2.3M Ω to 2k Ω as the diode block begins conducting. Inversely, the bias current increases with the same curve.

Rail-to-Rail Output Stage

The MAX4330–MAX4334 output stage can drive up to a $2k\Omega$ load and still typically swing within 125mV of the rails. Figure 3 shows the output voltage swing of a MAX4331 configured as a unity-gain buffer. The operating voltage is a single +3V supply, and the input voltage is 3Vp-p. The output swings to within 70mV of V_{EE} and 100mV of V_{CC} , even with the maximum load applied ($2k\Omega$ to mid-supply).

Driving a capacitive load can cause instability in many op amps, especially those with low quiescent current. The MAX4330–MAX4334 are stable for capacitive loads up to 150pF. The Capacitive Load Stability graph in the *Typical Operating Characteristics* gives the stable operating region for capacitive vs. resistive loads. Figures 4 and 5 show the response of the MAX4331 with an excessive capacitive load, compared with the response when a series resistor is added between the output and the capacitive load. The resistor improves the circuit's response by isolating the load capacitance from the op amp's output (Figure 6).

Applications Information

Power-Up

The MAX4330-MAX4334 outputs typically settle within 5µs after power-up. Using the test circuit of Figure 7, Figures 8 and 9 show the output voltage and supply current on power-up and power-down.

Shutdown Mode

The MAX4331/MAX4333 feature a low-power shutdown mode. When the shutdown pin (SHDN) is pulled low, the supply current drops to 9µA per amplifier (typical), the amplifier is disabled, and the outputs enter a high-impedance state. Pulling SHDN high or leaving it floating enables the amplifier. Figures 10 and 11 show the MAX4331/MAX4333's output voltage and supply-current responses to a shutdown pulse.

Single/Dual/Quad, Low-Power, Single-Supply, Rail-to-Rail I/O Op Amps with Shutdown

Figure 9. Power-Up/Down Supply Current

Figure 10. Shutdown Output Voltage Enable/Disable

Do not three-state $\overline{\text{SHDN}}$. Due to the output leakage currents of three-state devices and the small internal pull-up current for $\overline{\text{SHDN}}$, three-stating this pin could result in indeterminate logic levels, and could adversely affect op-amp operation.

The logic threshold for $\overline{\text{SHDN}}$ is always referred to V_{EE} , **not** GND. When using dual supplies, pull $\overline{\text{SHDN}}$ to V_{EE} to place the op amp in shutdown mode.

Power Supplies and Layout

The MAX4330-MAX4334 operate from a single +2.3V to +6.5V power supply, or from dual $\pm 1.15\text{V}$ to $\pm 3.25\text{V}$ supplies. For single-supply operation, bypass the power supply with a $0.1\mu\text{F}$ capacitor to ground (V_{EE}). For dual supplies, bypass both V_{CC} and V_{EE} with their own set of capacitors to ground.

Good layout technique helps optimize performance by decreasing the amount of stray capacitance at the op amp's inputs and outputs. To decrease stray capacitance, minimize trace lengths by placing external components close to the op amp's pins.
