

**THE DATASHEET OF
DC782A-V**

FEATURES

- **Sample Rate: 125Mps/105Mps**
- **Single 3V Supply (2.85V to 3.4V)**
- **Low Power: 395mW/320mW**
- **70.2dB SNR**
- **88dB SFDR**
- No Missing Codes
- Flexible Input: 1V_{P-P} to 2V_{P-P} Range
- 640MHz Full Power Bandwidth S/H
- Clock Duty Cycle Stabilizer
- Shutdown and Nap Modes
- Pin Compatible Family
 - 125Mps: LTC2253 (12-Bit), LTC2255 (14-Bit)
 - 105Mps: LTC2252 (12-Bit), LTC2254 (14-Bit)
 - 80Mps: LTC2229 (12-Bit), LTC2249 (14-Bit)
 - 65Mps: LTC2228 (12-Bit), LTC2248 (14-Bit)
 - 40Mps: LTC2227 (12-Bit), LTC2247 (14-Bit)
 - 25Mps: LTC2226 (12-Bit), LTC2246 (14-Bit)
 - 10Mps: LTC2225 (12-Bit), LTC2245 (14-Bit)
- 32-Pin (5mm × 5mm) QFN Package

APPLICATIONS

- Wireless and Wired Broadband Communication
- Imaging Systems
- Ultrasound
- Spectral Analysis
- Portable Instrumentation

DESCRIPTION

The LTC[®]2253/LTC2252 are 12-bit 125Mps/105Mps, low power 3V A/D converters designed for digitizing high frequency, wide dynamic range signals. The LTC2253/LTC2252 are perfect for demanding imaging and communications applications with AC performance that includes 70.1dB SNR and 85dB SFDR for signals at the Nyquist frequency.

DC specs include $\pm 0.3\text{LSB INL (typ)}$, $\pm 0.15\text{LSB DNL (typ)}$ and no missing codes over temperature. The transition noise is a low $0.32\text{LSB}_{\text{RMS}}$.

A single 3V supply allows low power operation. A separate output supply allows the outputs to drive 0.5V to 3.3V logic.

A single-ended CLK input controls converter operation. An optional clock duty cycle stabilizer allows high performance at full speed for a wide range of clock duty cycles.

LT, LTC and LT are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

TYPICAL APPLICATION

LTC2253: SNR vs Input Frequency, -1dB, 2V Range, 125Mps

LTC2253/LTC2252

ABSOLUTE MAXIMUM RATINGS

$OV_{DD} = V_{DD}$ (Notes 1, 2)

Supply Voltage (V_{DD})	4V
Digital Output Ground Voltage (OGND)	-0.3V to 1V
Analog Input Voltage (Note 3)	-0.3V to ($V_{DD} + 0.3V$)
Digital Input Voltage	-0.3V to ($V_{DD} + 0.3V$)
Digital Output Voltage	-0.3V to ($OV_{DD} + 0.3V$)
Power Dissipation	1500mW
Operating Temperature Range		
LTC2253C, LTC2252C	0°C to 70°C
LTC2253I, LTC2252I	-40°C to 85°C
Storage Temperature Range	-65°C to 125°C

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: All voltage values are with respect to ground with GND and OGND wired together (unless otherwise noted).

Note 3: When these pin voltages are taken below GND or above V_{DD} , they will be clamped by internal diodes. This product can handle input currents of greater than 100mA below GND or above V_{DD} without latching.

Note 4: $V_{DD} = 3\text{V}$, $f_{\text{SAMPLE}} = 125\text{MHz}$ (LTC2253) or 105MHz (LTC2252), input range = $2V_{P-P}$ with differential drive, clock duty cycle stabilizer on, unless otherwise noted.

Note 5: Integral nonlinearity is defined as the deviation of a code from a straight line passing through the actual endpoints of the transfer curve. The deviation is measured from the center of the quantization band.

Note 6: Offset error is the offset voltage measured from -0.5LSB when the output code flickers between 0000 0000 0000 and 1111 1111 1111.

Note 7: Guaranteed by design, not subject to test.

Note 8: $V_{DD} = 3\text{V}$, $f_{\text{SAMPLE}} = 125\text{MHz}$ (LTC2253) or 105MHz (LTC2252), input range = $1V_{P-P}$ with differential drive.

Note 9: Recommend operating conditions.

PIN FUNCTIONS

A_{IN+} (Pin 1): Positive Differential Analog Input.

A_{IN-} (Pin 2): Negative Differential Analog Input.

REFH (Pins 3, 4): ADC High Reference. Short together and bypass to pins 5, 6 with a 0.1 μ F ceramic chip capacitor as close to the pin as possible. Also bypass to pins 5, 6 with an additional 2.2 μ F ceramic chip capacitor and to ground with a 1 μ F ceramic chip capacitor.

REFL (Pins 5, 6): ADC Low Reference. Short together and bypass to pins 3, 4 with a 0.1 μ F ceramic chip capacitor as close to the pin as possible. Also bypass to pins 3, 4 with an additional 2.2 μ F ceramic chip capacitor and to ground with a 1 μ F ceramic chip capacitor.

V_{DD} (Pins 7, 32): 3V Supply. Bypass to GND with 0.1 μ F ceramic chip capacitors.

GND (Pin 8): ADC Power Ground.

CLK (Pin 9): Clock Input. The input sample starts on the positive edge.

SHDN (Pin 10): Shutdown Mode Selection Pin. Connecting SHDN to GND and \overline{OE} to GND results in normal operation with the outputs enabled. Connecting SHDN to GND and \overline{OE} to V_{DD} results in normal operation with the outputs at high impedance. Connecting SHDN to V_{DD} and \overline{OE} to GND results in nap mode with the outputs at high impedance. Connecting SHDN to V_{DD} and \overline{OE} to V_{DD} results in sleep mode with the outputs at high impedance.

\overline{OE} (Pin 11): Output Enable Pin. Refer to SHDN pin function.

NC (Pins 12, 13): Do Not Connect These Pins.

D0 – D11 (Pins 14, 15, 16, 17, 18, 19, 22, 23, 24, 25, 26, 27): Digital Outputs. D11 is the MSB.

OGND (Pin 20): Output Driver Ground.

OV_{DD} (Pin 21): Positive Supply for the Output Drivers. Bypass to ground with 0.1 μ F ceramic chip capacitor. OV_{DD} can be set to 0.5V to 3.6V.

OF (Pin 28): Over/Under Flow Output. High when an over or under flow has occurred.

MODE (Pin 29): Output Format and Clock Duty Cycle Stabilizer Selection Pin. Connecting MODE to GND selects offset binary output format and turns the clock duty cycle stabilizer off. 1/3 V_{DD} selects offset binary output format and turns the clock duty cycle stabilizer on. 2/3 V_{DD} selects 2's complement output format and turns the clock duty cycle stabilizer on. V_{DD} selects 2's complement output format and turns the clock duty cycle stabilizer off.

SENSE (Pin 30): Reference Programming Pin. Connecting SENSE to V_{CM} selects the internal reference and a $\pm 0.5V$ input range. V_{DD} selects the internal reference and a $\pm 1V$ input range. An external reference greater than 0.5V and less than 1V applied to SENSE selects an input range of $\pm V_{SENSE}$. $\pm 1V$ is the largest valid input range.

V_{CM} (Pin 31): 1.5V Output and Input Common Mode Bias. Bypass to ground with 2.2 μ F ceramic chip capacitor.

GND (Exposed Pad) (Pin 33): ADC Power Ground. The exposed pad on the bottom of the package must be soldered to ground.

FUNCTIONAL BLOCK DIAGRAM

Figure 1. Functional Block Diagram

TIMING DIAGRAM

APPLICATIONS INFORMATION

DYNAMIC PERFORMANCE

Signal-to-Noise Plus Distortion Ratio

The signal-to-noise plus distortion ratio $[S/(N + D)]$ is the ratio between the RMS amplitude of the fundamental input frequency and the RMS amplitude of all other frequency components at the ADC output. The output is band limited to frequencies above DC to below half the sampling frequency.

Signal-to-Noise Ratio

The signal-to-noise ratio (SNR) is the ratio between the RMS amplitude of the fundamental input frequency and the RMS amplitude of all other frequency components except the first five harmonics and DC.

Total Harmonic Distortion

Total harmonic distortion is the ratio of the RMS sum of all harmonics of the input signal to the fundamental itself. The out-of-band harmonics alias into the frequency band between DC and half the sampling frequency. THD is expressed as:

$$\text{THD} = 20\text{Log} (\sqrt{V_2^2 + V_3^2 + V_4^2 + \dots + V_n^2}/V_1)$$

where V_1 is the RMS amplitude of the fundamental frequency and V_2 through V_n are the amplitudes of the second through n th harmonics. The THD calculated in this data sheet uses all the harmonics up to the fifth.

Intermodulation Distortion

If the ADC input signal consists of more than one spectral component, the ADC transfer function nonlinearity can produce intermodulation distortion (IMD) in addition to THD. IMD is the change in one sinusoidal input caused by the presence of another sinusoidal input at a different frequency.

If two pure sine waves of frequencies f_a and f_b are applied to the ADC input, nonlinearities in the ADC transfer function can create distortion products at the sum and difference frequencies of $m f_a \pm n f_b$, where m and $n = 0, 1, 2, 3$, etc. The 3rd order intermodulation products are $2f_a + f_b$, $2f_b + f_a$, $2f_a - f_b$ and $2f_b - f_a$. The intermodulation

distortion is defined as the ratio of the RMS value of either input tone to the RMS value of the largest 3rd order intermodulation product.

Spurious Free Dynamic Range (SFDR)

Spurious free dynamic range is the peak harmonic or spurious noise that is the largest spectral component excluding the input signal and DC. This value is expressed in decibels relative to the RMS value of a full scale input signal.

Input Bandwidth

The input bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3dB for a full scale input signal.

Aperture Delay Time

The time from when CLK reaches mid-supply to the instant that the input signal is held by the sample and hold circuit.

Aperture Delay Jitter

The variation in the aperture delay time from conversion to conversion. This random variation will result in noise when sampling an AC input. The signal to noise ratio due to the jitter alone will be:

$$\text{SNR}_{\text{JITTER}} = -20\text{log} (2\pi \cdot f_{\text{IN}} \cdot t_{\text{JITTER}})$$

CONVERTER OPERATION

As shown in Figure 1, the LTC2253/LTC2252 is a CMOS pipelined multistep converter. The converter has six pipelined ADC stages; a sampled analog input will result in a digitized value five cycles later (see the Timing Diagram section). For optimal AC performance the analog inputs should be driven differentially. For cost sensitive applications, the analog inputs can be driven single-ended with slightly worse harmonic distortion. The CLK input is single-ended. The LTC2253/LTC2252 has two phases of operation, determined by the state of the CLK input pin.

Each pipelined stage shown in Figure 1 contains an ADC, a reconstruction DAC and an interstage residue amplifier. In operation, the ADC quantizes the input to the stage and

APPLICATIONS INFORMATION

to set the DC input level or as a reference level to an op amp differential driver circuit. The V_{CM} pin must be bypassed to ground close to the ADC with a 2.2 μ F or greater capacitor.

Input Drive Impedance

As with all high performance, high speed ADCs, the dynamic performance of the LTC2253/LTC2252 can be influenced by the input drive circuitry, particularly the second and third harmonics. Source impedance and input reactance can influence SFDR. At the falling edge of CLK, the sample-and-hold circuit will connect the 3.5pF sampling capacitor to the input pin and start the sampling period. The sampling period ends when CLK rises, holding the sampled input on the sampling capacitor. Ideally the input circuitry should be fast enough to fully charge the sampling capacitor during the sampling period $1/(2F_{ENCODE})$; however, this is not always possible and the incomplete settling may degrade the SFDR. The sampling glitch has been designed to be as linear as possible to minimize the effects of incomplete settling.

For the best performance, it is recommended to have a source impedance of 100 Ω or less for each input. The source impedance should be matched for the differential inputs. Poor matching will result in higher even order harmonics, especially the second.

Input Drive Circuits

Figure 3 shows the LTC2253/LTC2252 being driven by an RF transformer with a center tapped secondary. The secondary center tap is DC biased with V_{CM} , setting the ADC input signal at its optimum DC level. Terminating on the transformer secondary is desirable, as this provides a common mode path for charging glitches caused by the sample and hold. Figure 3 shows a 1:1 turns ratio transformer. Other turns ratios can be used if the source impedance seen by the ADC does not exceed 100 Ω for each ADC input. A disadvantage of using a transformer is the loss of low frequency response. Most small RF transformers have poor performance at frequencies below 1MHz.

Figure 4 demonstrates the use of a differential amplifier to convert a single ended input signal into a differential input signal. The advantage of this method is that it provides low

frequency input response; however, the limited gain bandwidth of most op amps will limit the SFDR at high input frequencies.

Figure 5 shows a single-ended input circuit. The impedance seen by the analog inputs should be matched. This circuit is not recommended if low distortion is required.

The 25 Ω resistors and 12pF capacitor on the analog inputs serve two purposes: isolating the drive circuitry from the

Figure 3. Single-Ended to Differential Conversion Using a Transformer

Figure 4. Differential Drive with an Amplifier

Figure 5. Single-Ended Drive

APPLICATIONS INFORMATION

sample-and-hold charging glitches and limiting the wideband noise at the converter input.

For input frequencies above 70MHz, the input circuits of Figure 6, 7 and 8 are recommended. The balun transformer gives better high frequency response than a flux coupled center tapped transformer. The coupling capacitors allow the analog inputs to be DC biased at 1.5V. In Figure 8, the series inductors are impedance matching elements that maximize the ADC bandwidth.

Reference Operation

Figure 9 shows the LTC2253/LTC2252 reference circuitry consisting of a 1.5V bandgap reference, a difference amplifier and switching and control circuit. The internal voltage reference can be configured for two pin selectable input ranges of 2V ($\pm 1V$ differential) or 1V ($\pm 0.5V$ differential). Tying the SENSE pin to V_{DD} selects the 2V range; tying the SENSE pin to V_{CM} selects the 1V range.

The 1.5V bandgap reference serves two functions: its output provides a DC bias point for setting the common mode voltage of any external input circuitry; additionally, the reference is used with a difference amplifier to generate the differential reference levels needed by the internal ADC circuitry. An external bypass capacitor is required for the 1.5V reference output, V_{CM} . This provides a high frequency low impedance path to ground for internal and external circuitry.

Figure 6. Recommended Front End Circuit for Input Frequencies Between 70MHz and 170MHz

Figure 7. Recommended Front End Circuit for Input Frequencies Between 170MHz and 300MHz

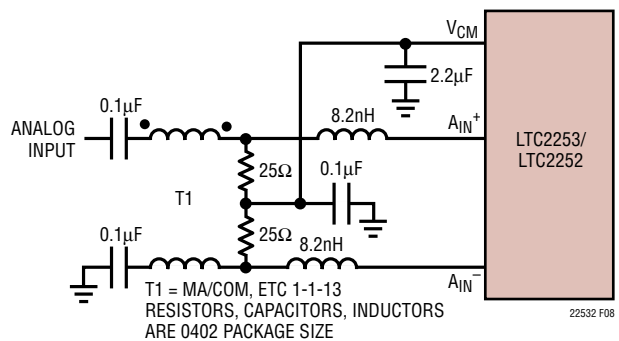

Figure 8. Recommended Front End Circuit for Input Frequencies Above 300MHz

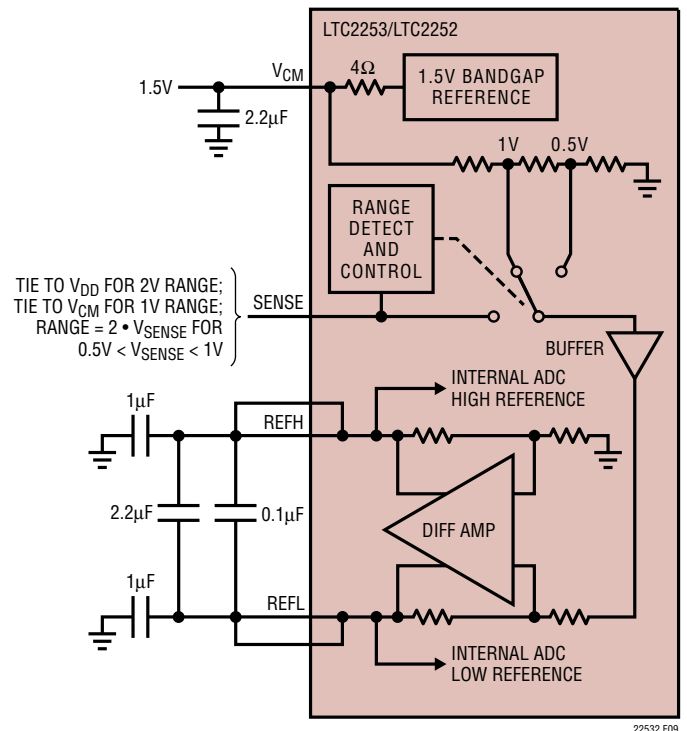

Figure 9. Equivalent Reference Circuit

APPLICATIONS INFORMATION

The difference amplifier generates the high and low reference for the ADC. High speed switching circuits are connected to these outputs and they must be externally bypassed. Each output has two pins. The multiple output pins are needed to reduce package inductance. Bypass capacitors must be connected as shown in Figure 9.

Other voltage ranges in-between the pin selectable ranges can be programmed with two external resistors as shown in Figure 10. An external reference can be used by applying its output directly or through a resistor divider to SENSE. It is not recommended to drive the SENSE pin with a logic device. The SENSE pin should be tied to the appropriate level as close to the converter as possible. If the SENSE pin is driven externally, it should be bypassed to ground as close to the device as possible with a 1 μ F ceramic capacitor.

Figure 10. 1.5V Range ADC

Input Range

The input range can be set based on the application. The 2V input range will provide the best signal-to-noise performance while maintaining excellent SFDR. The 1V input range will have better SFDR performance, but the SNR will degrade by 4.2dB.

Driving the Clock Input

The CLK input can be driven directly with a CMOS or TTL level signal. A sinusoidal clock can also be used along with a low jitter squaring circuit before the CLK pin (Figure 11).

The noise performance of the LTC2253/LTC2252 can depend on the clock signal quality as much as on the analog input. Any noise present on the clock signal will result in additional aperture jitter that will be RMS summed with the inherent ADC aperture jitter.

In applications where jitter is critical, such as when digitizing high input frequencies, use as large an amplitude as possible. Also, if the ADC is clocked with a sinusoidal signal, filter the CLK signal to reduce wideband noise and distortion products generated by the source.

Figures 12 and 13 show alternatives for converting a differential clock to the single-ended CLK input. The use of

Figure 11. Sinusoidal Single-Ended CLK Drive

IF LVDS USE FIN1002 OR FIN1018.
FOR PECL, USE AZ1000ELT21 OR SIMILAR

Figure 12. CLK Drive Using an LVDS or PECL to CMOS Converter

Figure 13. LVDS or PECL CLK Drive Using a Transformer

APPLICATIONS INFORMATION

a transformer provides no incremental contribution to phase noise. The LVDS or PECL to CMOS translators provide little degradation below 70MHz, but at 140MHz will degrade the SNR compared to the transformer solution. The nature of the received signals also has a large bearing on how much SNR degradation will be experienced. For high crest factor signals such as WCDMA or OFDM, where the nominal power level must be at least 6dB to 8dB below full scale, the use of these translators will have a lesser impact.

The transformer in the example may be terminated with the appropriate termination for the signaling in use. The use of a transformer with a 1:4 impedance ratio may be desirable in cases where lower voltage differential signals are considered. The center tap may be bypassed to ground through a capacitor close to the ADC if the differential signals originate on a different plane. The use of a capacitor at the input may result in peaking, and depending on transmission line length may require a 10Ω to 20Ω ohm series resistor to act as both a low pass filter for high frequency noise that may be induced into the clock line by neighboring digital signals, as well as a damping mechanism for reflections.

Maximum and Minimum Conversion Rates

The maximum conversion rate for the LTC2253/LTC2252 is 125Msps (LTC2253) and 105Msps (LTC2252). The lower limit of the LTC2253/LTC2252 sample rate is determined by droop of the sample-and-hold circuits. The pipelined architecture of this ADC relies on storing analog signals on small valued capacitors. Junction leakage will discharge the capacitors. The specified minimum operating frequency for the LTC2253/LTC2252 is 1Msps.

Clock Duty Cycle Stabilizer

An optional clock duty cycle stabilizer circuit ensures high performance even if the input clock has a non 50% duty cycle. Using the clock duty cycle stabilizer is recommended for most applications. To use the clock duty cycle stabilizer, the MODE pin should be connected to 1/3V_{DD} or 2/3V_{DD} using external resistors.

This circuit uses the rising edge of the CLK pin to sample the analog input. The falling edge of CLK is ignored and the

internal falling edge is generated by a phase-locked loop. The input clock duty cycle can vary from 40% to 60% and the clock duty cycle stabilizer will maintain a constant 50% internal duty cycle. If the clock is turned off for a long period of time, the duty cycle stabilizer circuit will require a hundred clock cycles for the PLL to lock onto the input clock.

For applications where the sample rate needs to be changed quickly, the clock duty cycle stabilizer can be disabled. If the duty cycle stabilizer is disabled, care should be taken to make the sampling clock have a 50% (±5%) duty cycle.

DIGITAL OUTPUTS

Table 1 shows the relationship between the analog input voltage, the digital data bits and the overflow bit.

Table 1. Output Codes vs Input Voltage

A _{IN} ⁺ – A _{IN} [–] (2V Range)	OF	D11 – D0 (Offset Binary)	D11 – D0 (2's Complement)

Digital Output Buffers

Figure 14 shows an equivalent circuit for a single output buffer. Each buffer is powered by OV_{DD} and OGND, isolated from the ADC power and ground. The additional N-channel transistor in the output driver allows operation down to low voltages. The internal resistor in series with the output makes the output appear as 50Ω to external circuitry and may eliminate the need for external damping resistors.

As with all high speed/high resolution converters, the digital output loading can affect the performance. The digital outputs of the LTC2253/LTC2252 should drive a minimal capacitive load to avoid possible interaction between the digital outputs and sensitive input circuitry. For

APPLICATIONS INFORMATION

Figure 14. Digital Output Buffer

full speed operation the capacitive load should be kept under 10pF.

Lower OV_{DD} voltages will also help reduce interference from the digital outputs.

Data Format

Using the MODE pin, the LTC2253/LTC2252 parallel digital output can be selected for offset binary or 2's complement format. Connecting MODE to GND or $1/3V_{DD}$ selects offset binary output format. Connecting MODE to $2/3V_{DD}$ or V_{DD} selects 2's complement output format. An external resistor divider can be used to set the $1/3V_{DD}$ or $2/3V_{DD}$ logic values. Table 2 shows the logic states for the MODE pin.

Table 2. MODE Pin Function

MODE Pin	Output Format	Clock Duty Cycle Stabilizer
0	Offset Binary	Off
$1/3V_{DD}$	Offset Binary	On
$2/3V_{DD}$	2's Complement	On
V_{DD}	2's Complement	Off

Overflow Bit

When OF outputs a logic high the converter is either overranged or underranged.

Output Driver Power

Separate output power and ground pins allow the output drivers to be isolated from the analog circuitry. The power supply for the digital output buffers, OV_{DD} , should be tied

to the same power supply as for the logic being driven. For example if the converter is driving a DSP powered by a 1.8V supply, then OV_{DD} should be tied to that same 1.8V supply.

OV_{DD} can be powered with any voltage from 500mV up to 3.6V. $OGND$ can be powered with any voltage from GND up to 1V and must be less than OV_{DD} . The logic outputs will swing between $OGND$ and OV_{DD} .

Output Enable

The outputs may be disabled with the output enable pin, \overline{OE} . \overline{OE} high disables all data outputs including OF. The data access and bus relinquish times are too slow to allow the outputs to be enabled and disabled during full speed operation. The output Hi-Z state is intended for use during long periods of inactivity.

Sleep and Nap Modes

The converter may be placed in shutdown or nap modes to conserve power. Connecting SHDN to GND results in normal operation. Connecting SHDN to V_{DD} and \overline{OE} to V_{DD} results in sleep mode, which powers down all circuitry including the reference and typically dissipates 1mW. When exiting sleep mode it will take milliseconds for the output data to become valid because the reference capacitors have to recharge and stabilize. Connecting SHDN to V_{DD} and \overline{OE} to GND results in nap mode, which typically dissipates 15mW. In nap mode, the on-chip reference circuit is kept on, so that recovery from nap mode is faster than that from sleep mode, typically taking 100 clock cycles. In both sleep and nap modes, all digital outputs are disabled and enter the Hi-Z state.

Grounding and Bypassing

The LTC2253/LTC2252 require a printed circuit board with a clean, unbroken ground plane. A multilayer board with an internal ground plane is recommended. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the ADC.

High quality ceramic bypass capacitors should be used at the V_{DD} , OV_{DD} , V_{CM} , REFH, and REFL pins. Bypass capacitors must be located as close to the pins as possible. Of

225321a

APPLICATIONS INFORMATION

particular importance is the 0.1 μ F capacitor between REFH and REFL. This capacitor should be placed as close to the device as possible (1.5mm or less). A size 0402 ceramic capacitor is recommended. The large 2.2 μ F capacitor between REFH and REFL can be somewhat further away. The traces connecting the pins and bypass capacitors must be kept short and should be made as wide as possible.

The LTC2253/LTC2252 differential inputs should run parallel and close to each other. The input traces should be as short as possible to minimize capacitance and to minimize noise pickup.

Heat Transfer

Most of the heat generated by the LTC2253/LTC2252 is transferred from the die through the bottom-side exposed pad and package leads onto the printed circuit board. For good electrical and thermal performance, the exposed pad should be soldered to a large grounded pad on the PC board. It is critical that all ground pins are connected to a ground plane of sufficient area.

Clock Sources for Undersampling

Undersampling raises the bar on the clock source and the higher the input frequency, the greater the sensitivity to clock jitter or phase noise. A clock source that degrades SNR of a full-scale signal by 1dB at 70MHz will degrade SNR by 3dB at 140MHz, and 4.5dB at 190MHz.

In cases where absolute clock frequency accuracy is relatively unimportant and only a single ADC is required, a 3V canned oscillator from vendors such as Saronix or Vectron can be placed close to the ADC and simply connected directly to the ADC. If there is any distance to the ADC, some source termination to reduce ringing that may occur even over a fraction of an inch is advisable. You must not allow the clock to overshoot the supplies or

performance will suffer. Do not filter the clock signal with a narrow band filter unless you have a sinusoidal clock source, as the rise and fall time artifacts present in typical digital clock signals will be translated into phase noise.

The lowest phase noise oscillators have single-ended sinusoidal outputs, and for these devices the use of a filter close to the ADC may be beneficial. This filter should be close to the ADC to both reduce roundtrip reflection times, as well as reduce the susceptibility of the traces between the filter and the ADC. If you are sensitive to close-in phase noise, the power supply for oscillators and any buffers must be very stable, or propagation delay variation with supply will translate into phase noise. Even though these clock sources may be regarded as digital devices, do not operate them on a digital supply. If your clock is also used to drive digital devices such as an FPGA, you should locate the oscillator, and any clock fan-out devices close to the ADC, and give the routing to the ADC precedence. The clock signals to the FPGA should have series termination at the source to prevent high frequency noise from the FPGA disturbing the substrate of the clock fan-out device. If you use an FPGA as a programmable divider, you must re-time the signal using the original oscillator, and the re-timing flip-flop as well as the oscillator should be close to the ADC, and powered with a very quiet supply.

For cases where there are multiple ADCs, or where the clock source originates some distance away, differential clock distribution is advisable. This is advisable both from the perspective of EMI, but also to avoid receiving noise from digital sources both radiated, as well as propagated in the waveguides that exist between the layers of multi-layer PCBs. The differential pairs must be close together, and distanced from other signals. The differential pair should be guarded on both sides with copper distanced at least 3x the distance between the traces, and grounded with vias no more than 1/4 inch apart.
