

**THE DATASHEET OF
LTC1550LCMS8-2#TRPBF**

Low Noise, Switched Capacitor Regulated Voltage Inverters

FEATURES

- Regulated Negative Voltage from a Single Positive Supply
- Low Output Ripple: Less Than 1mV_{p-p} Typ
- High Charge Pump Frequency: 900kHz
- Small Charge Pump Capacitors: 0.1μF
- Requires Only Four External Capacitors
- Fixed -4.1V, -2.5V, -2V or Adjustable Output
- Shutdown Mode Drops Supply Current to <1μA
- High Output Current: Up to 20mA (Depending on V_{CC} to V_{OUT} Range)
- Output Regulation: 2.5% Over Line, Load and Temperature
- Available in 8-Lead MSOP, 8-Lead Narrow SO and 16-Lead Narrow SSOP

APPLICATIONS

- GaAs FET Bias Generators
- Negative Supply Generators
- Battery-Powered Systems
- Single Supply Applications

DESCRIPTION

The LTC[®]1550L/LTC1551L are switched capacitor charge pump voltage inverters which include internal linear post-regulators to minimize output ripple. The LTC1550L fixed output voltage versions include -4.1V, -2.5V and -2V with ripple voltages typically below 1mV_{p-p}. The LTC1550L is also available in an adjustable output voltage version. The LTC1550L/LTC1551L are ideal for use as bias voltage generators for GaAs transmitter FETs in portable RF and cellular telephone applications.

The LTC1550L/LTC1551L operate from single 2.7V to 5.5V supplies and draw typical quiescent currents of 3.5mA with a 5V supply. Each device includes a TTL compatible Shutdown pin which drops supply current to 0.2μA typically. The LTC1550L Shutdown pin is active low (SHDN), while the LTC1551L Shutdown pin is active high (SHDN). Only four external components are required: an input bypass capacitor, two 0.1μF charge pump capacitors and a filter capacitor at the linear regulator output. The adjustable LTC1550L/LTC1551L require two additional resistors to set the output voltage. The LTC1550L/LTC1551L will supply up to 20mA (depending on V_{CC} to V_{OUT} range), while maintaining guaranteed output regulation of ±2.5%.

Both fixed voltage and adjustable LTC1550L/LTC1551L are available in 8-lead MSOP and SO plastic packages: the adjustable LTC1550L is also available in a 16-pin SSOP with the REG pin.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: All currents into device pins are positive; all currents out of device pins are negative. All voltages are referenced to ground unless otherwise specified. All typicals are given at $T_A = 25^\circ\text{C}$.

Note 3: The LTC1550LC/LTC1551LC are guaranteed to meet specified performance from 0°C to 70°C and are designed, characterized and expected to meet these extended temperature limits, but are not tested at -40°C and 85°C . The LTC1550LI is guaranteed to meet the extended temperature limits.

PIN FUNCTIONS

SHDN: Shutdown (TTL Compatible). This pin is active low ($\overline{\text{SHDN}}$) for the LTC1550L and active high (SHDN) for the LTC1551L. When this pin is at V_{CC} (GND for LTC1551L), the LTC1550L operates normally. When SHDN is pulled low (SHDN pulled high for LTC1551L), the LTC1550L enters shutdown mode. In shutdown, the charge pump stops, the output collapses to 0V, and the quiescent current drops typically to 0.2 μ A. The $\overline{\text{SHDN}}$ pin for the LTC1550L is a high impedance input and has no internal pull-up. The user must supply a resistor or current source pull-up to default the LTC1550L into normal operation. The SHDN pin for the LTC1551L has an internal 5 μ A typical pull-down that defaults the LTC1551L into normal operation.

V_{CC} : Power Supply. V_{CC} requires an input voltage between 2.7V and 5.25V. Certain combinations of output voltage and output load current may place additional restrictions on the required input voltage. Consult the Electrical Characteristics table and Typical Performance Characteristics for guaranteed test points. The difference between the input voltage and output should not exceed 10.5V or damage to the chip may occur. V_{CC} must be bypassed directly to PGND (GND for 8-pin packages) with at least a 0.1 μ F capacitor placed in close proximity to the chip. A 1 μ F or larger low ESR bypass capacitor is recommended to minimize noise and ripple at the output. A surface mount ceramic capacitor is recommended.

$C1^+$: C1 Positive Input. Connect a 0.1 μ F capacitor between $C1^+$ and $C1^-$.

V_{OUT} : Negative Voltage Output. This pin must be bypassed with a 4.7 μ F or larger capacitor to ensure regulator loop stability. LTC recommends at least 10 μ F to achieve the specified output ripple. The output capacitor should be a moderate ESR capacitor, and not a very low ESR capacitor, as the zero in the feedback loop (formed by the ESR and the output capacitor) provides phase lead to the linear regulator feedback loop. Using very low ESR output capacitors will result in the output oscillating. A low ESR 0.1 μ F capacitor is recommended in parallel with the main output capacitor to minimize high frequency spikes at the output. The ground connection for the output capacitor

should connect directly to the V_{CC} and CP_{OUT} bypass capacitors, as well as to the GND of the LTC1550L/LTC1551L. LTC recommends a separate trace for the V_{OUT} capacitor ground connection to minimize noise.

$C1^-$: C1 Negative Input. Connect a 0.1 μ F capacitor from $C1^+$ to $C1^-$.

GND: Ground. Connect to a low impedance ground. A ground plane will help minimize regulation errors.

CP_{OUT} : Negative Charge Pump Output. This pin requires a 0.1 μ F storage capacitor to ground. In order to achieve ripple on the output voltage of less than 1mV, the ground connection for the CP_{OUT} capacitor must tie directly to the bottom of the V_{CC} bypass capacitor and at the GND pin of the LTC1550L/LTC1551L. This minimizes the AC current path for the charge pump.

REG: This is an open-drain output that pulls low when the output voltage is within 5% of the set value. It will sink 4mA to ground with a 5V supply. The external circuitry must provide a pull-up or REG will not swing high. The voltage at REG may exceed V_{CC} and can be pulled up to 6V above ground without damage. For the LTC1550L adjustable voltage version, the REG pin is only available in the 16-lead GN package.

ADJ (for adjustable versions): This is the feedback point for the external resistor divider string. Connect a divider string from GND to V_{OUT} with the divided tap connected to ADJ. Note that the resistor string needs to be connected “upside-down” from a negative regulator. See the Applications Information section for hook-up details.

GN PACKAGE ONLY

PGND: Power Ground. Connect to a low impedance ground. PGND should be connected to the same potential as AGND.

AGND: Analog Ground. Connect to a low impedance ground. AGND should be connected to a ground plane to minimize regulation errors.

NC: No Internal Connection.

APPLICATIONS INFORMATION

OVERVIEW

The LTC1550L/LTC1551L are switched capacitor, inverting charge pumps with internal linear post-regulators. The LTC1550L/LTC1551L provide a regulated, low ripple output at up to 20mA load current with the appropriate input voltage as output load current depends on the input/output voltage combination. Consult the graph provided in the Typical Performance Characteristics section and the Electrical Characteristics table for guaranteed test points. The LTC1550L/LTC1551L are ideal for use as bias voltage

generators for GaAs transmitter FETs in portable RF and cellular telephone applications. The LTC1550L features an active-low Shutdown pin (SHDN) that drops quiescent current to below $1\mu\text{A}$. The LTC1551L is identical to the LTC1550L, except that the Shutdown pin is active-high (SHDN). All members of the LTC1550L/LTC1551L family feature a 900kHz charge pump frequency. The LTC1550L/LTC1551L come standard with fixed -4.1V , -2.5V , -2V and adjustable output voltages. The LTC1550L/LTC1551L can be configured for other fixed output voltages; contact Linear Technology for more information.

APPLICATIONS INFORMATION

The LTC1550L/LTC1551L consist of two major blocks (see Block Diagram): an inverting charge pump and a negative linear regulator. The charge pump uses two external capacitors, C1 and C_{CP} to generate a negative voltage at CP_{OUT}. It operates by charging and discharging C1 on alternate phases of the internal 900kHz clock. C1 is initially charged to V_{CC} through switches S1 and S3. When the internal clock changes phase, S1 and S3 open and S2 and S4 close, shorting the positive side of C1 to ground. This forces the negative side of C1 below ground, and charge is transferred to C_{CP} through S4. As this cycle repeats, the magnitude of the negative voltage approaches V_{CC}. The 900kHz internal clock frequency helps keep noise out of the 400kHz to 600kHz IF bands commonly used by portable radio frequency systems and reduces the size of the external capacitors required. Most applications can use standard 0.1μF ceramic capacitors for C1 and C_{CP}. Increasing C1 and C_{CP} beyond 0.1μF has little effect on the output ripple or the output current capacity of the LTC1550L/LTC1551L.

The negative voltage at CP_{OUT} supplies the input to the negative regulator block. This block consists of an N-channel MOSFET pass device and a feedback amplifier that monitors the output voltage and compares it to the internal reference. The regulated output appears at the V_{OUT} pin. The regulation loop is optimized for fast transient response, enabling it to remove most of the switching artifacts present at the CP_{OUT} pin. Output ripple is typically below 1mV_{P-P} with output loads between 0mA and 10mA. The output voltage is set by a pair of internal divider resistors for the fixed voltage versions. The N-channel pass device minimizes dropout, allowing the output to remain in regulation with supply voltages as low as 2.7V for an output voltage of -2V. An output capacitor of at least 4.7μF from V_{OUT} to ground is required to keep the regulator loop stable; for optimum stability and minimum output ripple, at least 10μF is recommended.

Adjustable Hook-Up

For the adjustable LTC1550L/LTC1551L, the output voltage is set with a resistor divider from GND to V_{OUT} (Figure 2). Note that the internal reference and the internal feedback amplifier are set up as a positive-output regulator referenced to the V_{OUT} pin, not as a negative regulator

Figure 2. External Resistor Connections

referenced to ground. The output resistor divider must be set to provide 1.225V at the ADJ pin with respect to V_{OUT}. For example, a -3V output would require a 17.4k resistor from GND to ADJ, and a 12.1k resistor to V_{OUT}.

CAPACITOR SELECTION

The LTC1550L/LTC1551L requires four external capacitors: an input bypass capacitor, two 0.1μF charge pump capacitors and an output filter capacitor. The overall behavior of the LTC1550L/LTC1551L is strongly affected by how the capacitors are used, and by how the capacitors are laid out on the printed circuit board (PCB). In particular, the output capacitor's value and ESR have a significant effect on the output ripple and noise performance. In addition, the ground connections for the V_{CC} bypass capacitor, the CP_{OUT} capacitor and the V_{OUT} bypass capacitor must employ star-ground techniques at the GND pin of the LTC1550L/LTC1551L. Proper capacitor selection is critical for optimum performance of the LTC1550L/LTC1551L.

Output Ripple vs Output Capacitor

Figure 4 shows the effect of using different output capacitor values on the LTC1550L/LTC1551L output ripple. These curves are taken using the LTC1551L circuit in Figure 3, with C_{IN} = 2.2μF and I_{LOAD} = 5mA. The upper curve shows the performance with a standard tantalum capacitor alone and the lower curve shows that of the tantalum capacitor in parallel with a 0.1μF ceramic capacitor. As a general rule, larger output capacitors provide lower output ripple. To keep output voltage ripple below 1mV_{P-P}, 10μF, or greater, in parallel with a 0.1μF ceramic capacitor is required. To guarantee loop stability under all conditions, a minimum of 4.7μF is required at the output.

APPLICATIONS INFORMATION

Figure 4 shows a marked decrease in peak-to-peak output ripple when a 0.1μF ceramic capacitor is added in parallel with the tantalum output capacitor. The additional ripple with the tantalum output capacitor alone is mostly very high order harmonics of the 900kHz clock, which appear as sharp "spikes" at the output. The energy in these spikes is very small and they do not contribute to the RMS output voltage, but their peak-to-peak amplitude can be several millivolts under some conditions. A 0.1μF ceramic capacitor has significantly lower impedance at the spike frequency than a large tantalum capacitor, and eliminates most of these left-over switching spikes that the tantalum capacitor leaves behind. Figure 5 and 6 show scope photos of the output of Figure 4 with and without the additional ceramic capacitor at the output.

A series RC or LC filter can reduce high frequency output noise even further. Due to the high 900kHz switching frequency, not much R or L is required; a ferrite bead or a relatively long PC board trace in series with 0.1μF ceramic capacitor will usually keep the output ripple well below 1mV_{P-P}. Figure 1 shows an example of an ultralow noise -2V generator. The corresponding spectrum and spot noise plots for this circuit are shown in the Typical Performance Characteristics section.

Figure 3. Output Ripple Test Circuit

Figure 4. Output Ripple vs Output Capacitance

Figure 5. Output Ripple with 10μF Tantalum Capacitor

Figure 6. Output Ripple with 10μF Tantalum Capacitor Paralleled with 0.1μF Ceramic Capacitor

APPLICATIONS INFORMATION

Output Ripple vs Input Bypass Capacitor

The input bypass capacitor (C_{IN}) can also have a fairly significant impact on the output ripple. C_{IN} provides most of the LTC1550L/LTC1551L's supply current while it is charging the flying capacitor ($C1$). Inadequate input bypassing can cause the V_{CC} supply to dip when the charge pump switches, causing the output linear regulator to momentarily stop regulating. C_{IN} should be mounted as close to the LTC1550L/LTC1551L V_{CC} and GND pins as possible and its value should be significantly larger than

$C1$. Surface mount tantalum or ceramic capacitors with low ESR generally provide adequate performance. Figure 7 shows the LTC1550L/LTC1551L peak-to-peak output ripple vs C_{IN} , taken using the test circuit in Figure 3 with I_{LOAD} set at 5mA. C_{OUT} is a $10\mu\text{F}$ in parallel with a $0.1\mu\text{F}$ ceramic capacitor.

A $2.2\mu\text{F}$ surface mount ceramic capacitor at V_{CC} generally provides adequate output ripple performance for most applications.

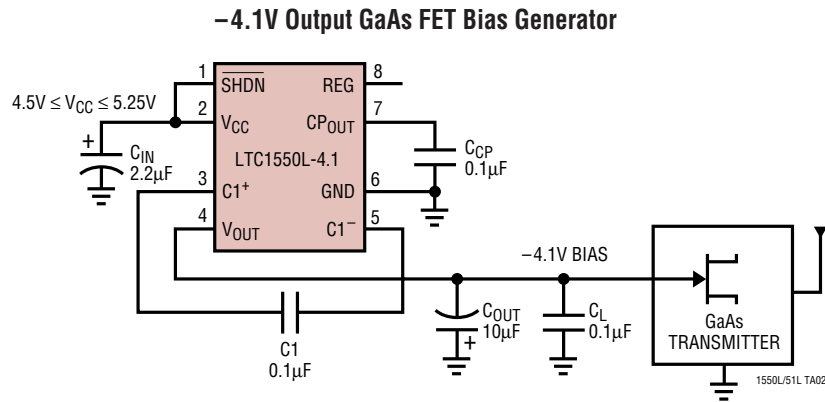

Figure 7. Output Ripple vs Input Bypass Capacitance

TYPICAL APPLICATION

PACKAGE DESCRIPTION Dimensions in inches (millimeters) unless otherwise noted.

GN Package
16-Lead Plastic SSOP (Narrow 0.150)
 (LTC DWG # 05-08-1641)

* DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006* (0.152mm) PER SIDE
 ** DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010* (0.254mm) PER SIDE

GN16 (SSOP) 1098

MS8 Package
8-Lead Plastic MSOP
 (LTC DWG # 05-08-1660)

* DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS. MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED 0.006* (0.152mm) PER SIDE
 ** DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS. INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.006* (0.152mm) PER SIDE

MSOP (MS8) 1098
