

# THE DATASHEET OF MAX358CPE

## Fault-Protected Analog Multiplexer

MAX358/359, HI-508A/509A

### General Description

Maxim's HI-508A and MAX358 are 8 channel single-ended (1 of 8) multiplexers with fault protection. Maxim's HI-509A and MAX359 are 4 channel differential (2 of 8) multiplexers with fault protection. Using a series N-channel, P-channel, N-channel structure, these multiplexers provide significantly improved fault protection. If the power supplies to the Maxim fault-protected multiplexer are inadvertently turned off while input voltages are still applied, *all* channels in the multiplexer are turned off, and only a few nanoamperes of leakage current will flow into the inputs. This protects not only the multiplexer and the circuitry driven by the multiplexer, but also protects the sensors or signal sources which drive the multiplexer.

The Maxim series N-channel, P-channel, N-channel protection structure has two significant advantages over the simple current limiting protection scheme of the first generation fault protected multiplexers. First, the Maxim protection scheme limits fault currents to nanoamp leakage values rather than many milliamperes. This prevents damage to sensors or other sensitive signal sources. Second, the Maxim fault-protected multiplexers can withstand a *continuous*  $\pm 35V$  overvoltage, unlike the first generation which has a continuous overvoltage limitation of about  $\pm 10V$  imposed by power dissipation considerations.

All digital inputs have logic thresholds of 0.8V and 2.4V, ensuring both TTL and CMOS compatibility without requiring pullup resistors. Break-before-make operation is guaranteed. Power supply currents have been reduced and typical power dissipation is less than 2 milliwatts.

### Applications

- Data Acquisition Systems
- Industrial and Process Control Systems
- Avionics Test Equipment
- Signal Routing between Systems

### Features

- ◆ Improved 2nd Source (See "Maxim Advantage" on 3rd and 5th page)
- ◆ All Switches Off with Power Supplies Off
- ◆ On Channel Turns OFF if Overvoltage Occurs
- ◆ Only Nanoamperes of Input Current under All Fault Conditions
- ◆ Latchup-proof Construction
- ◆ Operates from  $\pm 4.5$  to  $\pm 18V$  Supplies
- ◆ All Digital Inputs are TTL and CMOS Compatible

### Ordering Information

(Ordering Information is continued on last page.)

\*\* The substrate may be allowed to float or be tied to V<sup>-</sup> (JI CMOS).

### Pin Configuration

The "Maxim Advantage"™ signifies an upgraded quality level. At no additional cost we offer a second-source device that is subject to the following: guaranteed performance over temperature along with tighter test specifications on many key parameters; and device enhancements, when needed, that result in improved performance without changing the functionality.

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Note 2:** Ten nanoamps is the practical lower limit for high speed measurement in the production test environment.

**Note 3:** To drive from DTL/TTL Circuits, 1kΩ pull-up resistors to +5.0V supply are recommended.

**Note 4:** Digital input leakage is primarily due to the clamp diodes. Typical leakage is less than 1nA at +25°C.

## Fault-Protected Analog Multiplexer

- ◆ Only Nanoamps of Leakage Under Fault Conditions
- ◆ All Switches OFF With Power Supplies Off
- ◆ Channel Turns OFF When Overvoltage Occurs
- ◆ TTL Compatible, No Pullups Required
- ◆ Significantly Reduced Power Consumption
- ◆  $\pm 4.5V$  to  $\pm 18V$  Operation

## Fault-Protected Analog Multiplexer

MAX358/359, HI-508A/509A

Figure 7. Typical Data Acquisition Front End

### Typical Applications

Figure 7 shows a typical data acquisition system using the MAX358 multiplexer. Since the multiplexer is driving a high impedance input, its error is a function of its own resistance ( $R_{DS(ON)}$ ) times the multiplexer leakage current ( $I_{D(ON)}$ ) and the amplifier bias current ( $I_{BIAS}$ ):

$$\begin{aligned} V_{ERR} &= R_{DS(ON)} \times (I_{D(ON)} + I_{BIAS} (\text{MAX420})) \\ &= 1.5k \times (2nA + 30pA) \\ &= 3.05\mu V \text{ maximum error} \end{aligned}$$

In most cases, this error is low enough that pre-amplification of input signals is not needed, even with very low level signals, such as  $40\mu V/^\circ C$  from type J thermocouples.

In systems with fewer than 8 inputs, an unused channel can be connected to the system ground reference point for software zero correction. A second channel connected to the system voltage reference allows gain correction of the entire data acquisition system as well.

A MAX 420 precision op-amp is connected as a programmable gain amplifier, with gains ranging from 1 to 10,000. The guaranteed  $5\mu V$  unadjusted offset of the MAX420 maintains high signal accuracy, while programmable gain allows the output signal level to be scaled to the optimum range for the remainder of

the data acquisition system, normally a Sample/Hold and A/D. Since the gain-changing multiplexer is not connected to the external sensors, it can be either a DG508A multiplexer or the fault protected MAX358.

Input switching, however, must be done with a fault protected MAX358 multiplexer if it is to provide the level of protection and isolation required with most data acquisition inputs. Since external signal sources may continue to supply voltage when the multiplexer and system power are turned off, non-fault protected multiplexers, or even first-generation fault protected devices, will allow many milliamps of fault current to flow from outside sources into the multiplexer. The result could be damage to either the sensors or the multiplexer. A non-fault protected multiplexer will also allow input overvoltages to appear at its output, perhaps damaging Sample/Holds or A/Ds. Such input overdrives may also cause input-to-input shorts, allowing the high current output of one sensor to possibly damage another.

The MAX358 eliminates all of the above problems since it not only limits its output voltage to safe levels, with or without power applied ( $+V_{SUP}$  and  $-V_{SUP}$ ), but also turns all channels off when power is removed, drawing only sub-microamp fault currents from the inputs, and maintaining isolation between inputs for continuous overvoltages up to  $\pm 35V$ .

## Fault-Protected Analog Multiplexer

### Detailed Description Fault Protection Circuitry

Maxim's HI-508A/509A and MAX358/359 are fully fault-protected for continuous input voltages up to  $\pm 35V$ , whether or not the  $+V_{SUP}$  and  $-V_{SUP}$  power supplies are present. These devices use a "series FET" protection scheme which not only protects the multiplexer output from overvoltage, but also limits the input current to sub-microamp levels. This fault current is several orders of magnitude lower than the original manufacturer's HI-508A (several milliamperes), which uses 1 to 2k $\Omega$  protection resistors in series with parasitic diodes connected to  $+V_{SUP}$  and  $-V_{SUP}$ .

Figures 8 and 9 show how the series FET circuit protects against overvoltage conditions. When power is off, the gates of all three FETs are at ground. With a  $-25V$  input, N-channel FET Q1 is turned on by the  $+25V$  gate-to-source voltage. The P-channel device (Q2), however, has  $+25V$   $V_{GS}$  and is turned off, thereby preventing the input signal from reaching the output. If the input voltage is  $+25V$ , Q1 has a negative  $V_{GS}$ , which turns it off. Similarly, only sub-microamp leakage currents can flow from the output back to the input, since any voltage will turn off either Q1 or Q2.

Figure 10 shows the condition of an OFF channel with  $+V_{SUP}$  and  $-V_{SUP}$  present. As with Figures 8 and 9, either an N-channel or a P-channel device will be off for any input voltage from  $-35V$  to  $+35V$ . The leakage current with negative overvoltages will immediately drop to a few nanoamps at  $25^{\circ}C$ . For positive overvoltages that fault current will initially be 10 or 20 $\mu A$ , decaying over a few seconds to the nanoamp level. The time constant of this decay is caused by the discharge of stored charge from internal nodes and does not compromise the fault protection scheme.

Figure 11 shows the condition of the ON channel with  $+V_{SUP}$  and  $-V_{SUP}$  present. With input voltages less than  $\pm 10V$ , all three FETs are on and the input signal appears at the output. If the input voltage exceeds  $+V_{SUP}$  minus the N-channel threshold voltage ( $V_{TN}$ ), then the N-channel FET will turn off. For voltages more negative than  $-V_{SUP}$  minus the P-channel threshold ( $V_{TP}$ ), the P-channel device will turn off. Since  $V_{TN}$  is typically 1.5V and  $V_{TP}$  is typically 3V, the multiplexer's output swing is limited to about  $-12V$  to  $+13.5V$  with  $\pm 15V$  supplies.

# Fault-Protected Analog Multiplexer

**MAX358/359, HI-508A/509A**

The Typical Characteristics graphs show typical leakage vs. input voltage curves. Although the maximum rated overvoltage of these devices is  $\pm 35V$ , the MAX358/359 typically has excellent performance up to  $\pm 40V$ , providing additional margin for the unknown transients that exist in the real world. In summary, the MAX358/359 provides superior protection from all fault conditions, while using a standard, readily produced junction isolated CMOS process.

### Switching Characteristics and Charge Injection

Table 1 shows typical charge injection levels vs. power supply voltages and analog input voltage. Note that since the channels are well matched, the differential charge injection for the MAX359/HI-509A is typically less than 5 picocoulombs. The charge injection that occurs during switching creates a voltage transient whose magnitude is inversely proportional to the capacitance on the multiplexer output.

The channel-to-channel switching time is typically 600ns, with about 200ns of break before make delay. This 200ns break-before-make delay prevents the input-to-input short that would occur if two input channels were simultaneously connected to the output. In a typical data acquisition system such as Figure 7, the dominant delay is not the switching time of the MAX358 multiplexer, but is the settling time of the following amplifiers and S/H. Another limiting factor is the RC time constant of the multiplexer  $R_{DS(ON)}$  plus the signal source impedance multiplied by the load capacitance on the output of the multiplexer. Even with low signal source impedances, 100pF of capacitance on the multiplexer output will approximately double the settling time to 0.01% accuracy.

### Operation with Supply Voltages Other than $\pm 15V$

The main effect of supply voltages other than  $\pm 15V$  is the reduction in output signal range. The MAX358 limits the output voltage to about 1.5V below  $+V_{SUP}$  and about 3V above  $-V_{SUP}$ . In other words, the output swing is limited to +3.5V to -2V when operating from  $\pm 5V$ . The typical characteristics graphs show typical  $R_{DS(ON)}$  for  $\pm 15V$ ,  $\pm 10V$ , and  $\pm 5V$  power supplies. Maxim tests and guarantees the MAX358/359 for operation from  $\pm 4.5V$  to  $\pm 18V$  supplies. The switching delays are increased by about a factor of 2 at  $\pm 5V$ , but break-before-make action is preserved.

The MAX358/9 can be operated with a single +9V to +22V supply, as well as asymmetrical power supplies such as +15V and -5V. The digital threshold will remain approximately 1.6V above the Ground pin, and the analog characteristics such as  $R_{DS(ON)}$  are determined by the total voltage difference between  $+V_{SUP}$  and  $-V_{SUP}$ . Connect  $-V_{SUP}$  to 0V when operating with a +9V to +22V single supply.

The MAX358 digital threshold is relatively independent of the power supply voltages, going from a

**Table 1A. MAX358 AND HI-508A CHARGE INJECTION**

Supply Voltage	Analog Input Level	Injected Charge
$\pm 5V$	+1.7V	+100pC
	0V	+70pC
	-1.7V	+45pC
$\pm 10V$	+5V	+200pC
	0V	+130pC
	-5V	+60pC
$\pm 15V$	+10V	+300pC
	0V	+180pC
	-10V	+50pC

Test Conditions:  $C_L = 1000pF$  on multiplexer output; the tabulated analog input level is applied to channel 1; channels 2 through 8 inputs are open circuited.  $EN = +5V$ ,  $A_1 = A_2 = 0V$ ,  $A_0$  is toggled at 2kHz rate between 0V and 3V. +100 picocoulombs of charge creates a +100mV step when injected into a 1000pF load capacitance.

**Table 1B. MAX359 AND HI-509A CHARGE INJECTION**

Supply Voltage	Analog Input Level	Injected Charge		
		Out A	Out B	Differential A - B
$\pm 5V$	+1.7V	+105pC	+107pC	-2pC
	0V	+73pC	+74pC	-1pC
	-1.7V	+48pC	+50pC	-2pC
$\pm 10V$	+5V	+215pC	+220pC	-5pC
	0V	+135pC	+139pC	-4pC
	-5V	+62pC	+63pC	-1pC
$\pm 15V$	+10V	+325pC	+330pC	-5pC
	0V	+180pC	+185pC	-5pC
	-10V	+55pC	+55pC	0pC

Test Conditions:  $C_L = 1000pF$  on Out A and Out B; the tabulated analog input level is applied to inputs 1A and 1B; channels 2 through 4 are open circuited.  $EN = +5V$ ,  $A_1 = 0V$ ,  $A_0$  is toggled from 0V to 3V at a 2kHz rate.

typical 1.6V when  $+V_{SUP}$  is 15V to 1.5V typical with a  $5V +V_{SUP}$ . This means that Maxim HI-508/509A and MAX358/359 will operate with standard TTL logic levels, even with  $\pm 5V$  power supplies. In all cases, the threshold of the ENable pin is the same as the other logic inputs.

### Digital Interface Levels

The typical digital threshold of both the address lines and the enable pin is 1.6V, with a temperature coefficient of about  $-3mV/^\circ C$ . This ensures compatibility with 0.8V to 2.4V TTL logic swings over the entire temperature range. The digital threshold is relatively independent of the supply voltages, moving from 1.6V typical to 1.5V typical as the power supplies are reduced from  $\pm 15V$  to  $\pm 5V$ . In all cases, the digital threshold is referenced to the Ground pin.

The digital inputs can also be driven with CMOS logic

## Fault-Protected Analog Multiplexer

levels swinging from either +V<sub>SUP</sub> to -V<sub>SUP</sub> or from +V<sub>SUP</sub> to Ground. The digital input current is just a few nanoamps of leakage at all input voltage levels, with a guaranteed maximum of 1μA. The digital inputs are protected from ESD by a 30V zener diode between the input and +V<sub>SUP</sub>, and can be driven ±6V beyond the supplies without drawing excessive current.

### Operation as a Demultiplexer

The MAX358/9 will function as a demultiplexer, where the input is applied to the Output pin, and the Input pins are used as outputs. The MAX358/9 provides both break-before-make action and full fault protection when operated as a demultiplexer, unlike earlier generations of fault protected multiplexers.

### Channel-to-Channel Crosstalk, Off Isolation and Digital Feedthrough

At DC and low frequencies the channel-to-channel crosstalk is caused by variations in output leakage currents as the off channel input voltages are varied. The MAX358 output leakage varies only a few picoamps as all 7 off inputs are toggled from -10V to +10V. The output voltage change depends on the impedance level at the MAX358 output, which is R<sub>DS(ON)</sub> plus the input signal source resistance in most cases since the load driven by the MAX358 is usually a high impedance. For a signal source impedance of 10kΩ or lower, the DC crosstalk exceeds 120dB.

Table 2 shows typical AC crosstalk and off isolation performance. Digital feedthrough is masked by the analog charge injection when the output is enabled. When the output is disabled, the digital feedthrough is virtually unmeasurable, since the digital pins are physically isolated from the analog section by the

Ground and -V<sub>SUP</sub> pins. The groundplane formed by these lines is continued onto the MAX358/9 die to provide over 100dB isolation between the digital and analog sections.

**Table 2A. TYPICAL OFF ISOLATION REJECTION RATIO**

Frequency	100kHz	500kHz	1MHz
One Channel Driven	74dB	72dB	66dB
All Channels Driven	64dB	48dB	44dB

Test Conditions: V<sub>IN</sub> = 20V<sub>PK-PK</sub> at the tabulated frequency, R<sub>L</sub> = 1.5k between OUT and ground, EN = 0V.

$$OIRR = 20 \text{ Log } \frac{20V_{PK-PK}}{V_{OUT(PK-PK)}}$$

**Table 2B. TYPICAL CROSSTALK REJECTION RATIO**

Frequency	100kHz	500kHz	1MHz
R <sub>L</sub> = 1.5k	70dB	68dB	64dB
R <sub>L</sub> = 10k	62dB	46dB	42dB

Test Conditions: Specified R<sub>L</sub> connected from OUT to ground. EN = +5V, A<sub>0</sub> = A<sub>1</sub> = A<sub>2</sub> = +5V (Channel 1 selected). 20V<sub>PK-PK</sub> at the tabulated frequency is applied to Channel 2. All other channels are open circuited. Similar crosstalk rejection can be observed between any two channels.
